Introduction

Reports of psychic phenomena (collectively called *psi*) – from intuitive hunches and dreamlike premonitions to seemingly uncanny coincidences and successful

experiments in telepathy or remote viewing – have long tantalized scientists and philosophers. Yet these phenomena remain elusive, often defying repeatable demonstration despite numerous attempts. In recent decades, theoretical frameworks have emerged to explain *why* psi is so slippery. One of the most influential is Walter von Lucadou's **Model of Pragmatic Information (MPI)**, which reconceives psi not as a physical force or signal, but as a special kind of *entanglement-like correlation* within systems. This article provides an in-depth synthesis of MPI's perspective on psi and explores its relationship to major consciousness theories and a spectrum of anomalous phenomena. We will compare MPI with Penrose and Hameroff's Orch-OR quantum consciousness model and Michael Levin's "minds everywhere" framework, examine how MPI illuminates past discussions (e.g. "[Why Psi is So Hard to Prove](#)," "[The Greatest PSI Experiment Ever](#)," and "[When the Sacred Goes Mainstream](#)"), consider its resonance with models of enlightenment and nonduality, and finally apply MPI's principles to the taxonomy of psi-related anomalies – from dream precognition and psychokinesis to UFOs and Bigfoot. The goal is a rigorous yet accessible exploration of psi through the lens of MPI, drawing on both theoretical insights and practical implications.

The Model of Pragmatic Information (MPI): Foundations and Axioms

At its core, MPI approaches psi from a **systems theory** perspective. Rather than starting at the level of quantum particles or neural microstructures, MPI begins with the abstract organization of systems – whether those systems are individual minds, devices, or whole socio-psychological networks. Lucadou's insight was that many features of psi phenomena (non-local correlations, observer-dependent effects, etc.) resemble the principles of **quantum theory**, but they might operate at a higher level of description, not literally at the level of subatomic particles. To capture this, MPI leverages the formalism of **Generalized Quantum Theory (GQT)**, extending concepts like *complementarity* and *entanglement* to general systems (even non-physical ones).

Under MPI, a *psi effect* is defined as a **non-local, meaning-dependent correlation** between parts of an **organizationally closed system**. An organizationally closed system is one that maintains its identity through self-referential interactions – for example participant and experimenter forming a closed loop of expectations and feedback, or a person subconsciously interacting with their environment in a meaningful way. Within such a system, MPI posits there can arise **entanglement-like correlations** that are *non-causal* – that is, they are not mediated by any conventional signal or force, but by the *meaning* or information shared in the system. Crucially, these correlations are **structurally similar to quantum entanglement** (instantaneous and not distance-dependent), yet MPI does *not* insist they stem from actual quantum processes in the brain or space-time. In fact, Lucadou and colleagues explicitly avoid invoking new quantum physics for psi, arguing that doing so introduces unnecessary assumptions (e.g. that neurons sustain macroscopic quantum states). Instead, MPI treats psi as an emergent informational phenomenon: “*non-local entanglement-correlations in socio-psycho-physical, self-organizing systems*”.

*Abstract depiction of complex informational patterns and entangled connections. In MPI, **phenomena** are conceived as **entanglement-like correlations** within a self-contained system where mind and matter become linked by shared meaning rather than signal exchange.*

A cornerstone of MPI is the **NT axiom**, short for *Non-Transmission* (or *Non-Transfere* of information. This axiom is inspired by a fundamental property of quantum entanglement: no matter how strongly two particles are entangled, one cannot use t entanglement to send a message or controllable signal between them. Likewise, ME asserts that while psi represents real correlations, those correlations **cannot carry usable information** or be harnessed like a classical signal. Any attempt to exploit p for communication or reliable prediction will *inevitably disrupt or destroy the effect* – a built-in safeguard of nature. Lucadou summarizes this elegantly: “Any operationalization which would use the non-local correlation as a signal transfer makes the correlation vanish or change the effect in unpredictable ways.” This is essentially a no-gc

theorem for psychic signaling. The NT axiom has profound implications: it explains why psi phenomena are so often **subtle, evanescent, or unpredictable**, especially under rigorous observation. The moment one tries to pin them down to send a message or achieve a fixed outcome, the phenomenon “*melts*” away. Psi, in MPI’s phrase, belongs to the “**paradise of unintentional, holistic**” experience – as soon as one leaves that paradise with intent to exploit the effect, the magic is lost.

To formalize these ideas, MPI introduces the concept of **pragmatic information (I)** essentially information that has *meaningful effects* within the system. In an observational or psi interaction, pragmatic information is exchanged between the system and its environment (which could include other people or devices) and is defined by a balance between **reliability (R)** and **autonomy (A)** on the side of the closed system, and between **confirmation (B)** and **novelty (E)** on the side of the environment. Lucadou even proposes a fundamental relation: $I = R \times A = B \times E = n \times i$ (where i is a “minimal action of information”). In simple terms, this equation implies a kind of uncertainty principle: a psi interaction that is highly *reliable* (repeatable) will tend to be low in *autonomy* (i.e., only trivial or weak effects), whereas a highly autonomous, surprising psi effect will be fickle or hard to replicate (low reliability). Likewise, any observation yields a mix of confirmation (expected, known information) and novelty (unexpected information) – you can’t maximize both at once. This trade-off underlies why **dramatic psi manifestations tend to be one-offs**, while repeatable psi experiments see only tiny statistical deviations. It’s essentially a quantitative statement of the old parapsychological adage that *the harder you try, the more psi slips away*.

MPI therefore proposes two governing **laws of psi**: (1) Psi phenomena are manifestations of non-local entanglement correlations in self-organizing, closed systems, induced by the exchange of pragmatic information that actually *creates* and binds that system. (2) Any attempt to use those entanglement correlations to send a signal or achieve a fixed outcome will nullify or unpredictably alter the effect (the NT principle). From these laws, MPI is able to derive and explain several *characteristic features* observed in psi research over the years:

- **The Decline Effect:** Initial positive results in a psi experiment often “fade” with repetition. Over time or across exact replications, the hit rates tend to **decline toward chance**. MPI predicts this because repeated trials turn novelty (E) into confirmation (B); the meaning saturates and the entanglement correlation dissipates. For example, in the Princeton PEAR studies on mind-over-machine strong effect seen in early trials dwindled with each subsequent replication attempt. This is exactly what MPI would expect once the “pragmatic information” has been exhausted or the participants’ mindset shifts from exploratory to outcome-focused.
- **The Effect-Size vs. Reproducibility Trade-off:** In general, *the more dramatic a claimed psi effect, the less reliably it can be reproduced*, and conversely, the most repeatable psi results tend to be very small in magnitude. Spontaneous cases (such as a crisis telepathy where someone “just knew” a loved one was in danger) may have a vivid impact, but they can’t be summoned on demand. Controlled experiments accumulate significant evidence only through many trials and tiny deviations (like a 51% hit rate over thousands of guesses). MPI formalizes this inverse relationship through the $R \times A = \text{const.}$ equation: you can dial up reliability or autonomy, but not both. The entangled system seems to “protect” itself from exploitation by ensuring that any large effect is a fleeting gift, not a repeatable trick.
- **Elusiveness and Displacement:** Psi phenomena often **evasion detection** – when you look directly, they hide, and sometimes they **displace** to an unexpected variable. Researchers have noted that if you try to nail down *where* a psi effect occurs, it might vanish there and pop up elsewhere in the data (a so-called *rabbit hole* effect). J. B. Rhine, the pioneer of ESP research, spoke of an invisible “Shyness Effect” of psi. MPI provides a mechanism: because the entanglement correlation is holistic, when you isolate one channel to measure, the system may reroute the meaningful outcome to another channel that isn’t under such tight scrutiny. This is called the **displacement effect**. For instance, if a subject’s psychokinetic influence on a random number generator (RNG) is blocked or the RNG is made “too perfect,” the meaningful effect might appear not in the RNG output but in

say, fluctuations of the subject's physiological responses or some other concomitant variable that wasn't being judged. MPI suggests that *meaning will find a way* to manifest, but not in any form that breaks the NT axiom. As Lucadou puts it, from the inside view the subject may have the strong **impression of a force** ("mind over matter"), but from the outside view there's only correlation, no force, a "pseudo-signal" that cannot be externally captured as a consistent signal.

In summary, MPI paints a picture of psi as *real but fleeting* – a delicate dance of correlations that can only occur under particular conditions of significance, spontaneity, and lack of direct control. Psi is *nonlocal and acausal*, rooted in the structure of information and meaning rather than energy. It requires a kind of participatory openness (being in the "endo-perspective" or inside of the phenomenon) and collapses under excessive observation or utilitarian intent. This framework not only aligns psi with modern understandings of complexity and quantum information but also offers an explanation for why psi has not been integrated into technology or daily predictable use: by its very nature, it resists those outcomes.

Consciousness Beyond Computation? MPI vs. Orch-OR and Levin's Framework

Before diving deeper into MPI's implications, it is useful to contrast it with other theories tackling the mind-matter relationship and consciousness, particularly Penrose and Hameroff's **Orch-OR model** and Michael Levin's **Platonic emergent minds** framework. These will help highlight what MPI *does and does not* claim about reality.

Orch-OR: Quantum Collapse and Non-Computable Mind

One of the most high-profile theories of consciousness in the last few decades is Sir Roger Penrose and Dr. Stuart Hameroff's **Orchestrated Objective Reduction (Orch OR)** model. Penrose, a mathematician-physicist, argued that human consciousness

understanding (especially of mathematics) cannot be explained by any algorithmic or computational process – invoking Gödel’s incompleteness theorem to suggest the mind does something *non-computable*. He proposed that the only physical process that might be non-computable is the spontaneous **collapse of the quantum wavefunction**. In Penrose’s view, each quantum superposition has its own “blister” of space-time curvature, and when enough mass or energy is in superposition, gravity triggers a collapse (an “objective reduction”) that is neither deterministic nor random, but influenced by Platonic values or proto-consciousness embedded in fundamental space-time geometry en.wikipedia.org en.wikipedia.org. Hameroff, an anesthesiologist, partnered with Penrose and hypothesized that such quantum collapses could be happening inside **microtubules** – protein lattices within neurons – effectively making the brain a quantum computer orchestrating these reductions. According to Orch-OR, a *conscious moment* occurs when a quantum state in microtubules undergoes objective reduction; the coherence is “orchestrated” (regulated) by neural processes so that it isn’t random but meaningful. This would mean consciousness is rooted in exotic quantum physics: non-computable influences selecting the collapse outcomes, potentially even with *retrocausal* effects (some Orch-OR proponents speculated that quantum processes might allow influences that run backward in time, offering one way to account for puzzling timing of conscious awareness).

How does MPI compare with Orch-OR? On the surface, they address different questions: Orch-OR is a **theory of consciousness** (why our minds are not machines, and how brain physics might produce awareness), whereas MPI is a **theory of psi phenomena** (why we observe entanglement-like anomalies between mind and matter). However, they both grapple with the limits of classical, reductionist models. Orch-OR says classical neural networks can’t explain the **qualitative insight** of consciousness; MPI says classical signal-based models can’t explain the **acausal correlations** of psi. Both invoke an analogy to quantum principles – Penrose literally posits quantum events at the Planck scale, while Lucadou uses the formalisms of quantum theory in a generalized way. Perhaps the key philosophical difference is **where the mystery is placed**: Orch-OR locates the non-local, non-computable element in the fundamental

physical substrate (tiny quantum collapses in tubulins guided by space-time geometry en.wikipedia.org, whereas MPI locates it at the level of **systems and information**, agnostic to the substrate (the entanglement could be happening in a purely informational state-space of the psychosocial system, without requiring microscopic quantum coherence in neurons).

MPI is largely **agnostic** about the brain's micro-physics. It does not rule out quantum processes in biology (and indeed, the formal math is borrowed from quantum theory but it doesn't demand them either. In fact, Lucadou et al. explicitly caution against assuming psi must be "quantum gravity magic" – they point out that mental phenomena may not need to piggyback on fragile quantum states, and that invoking such states raises tricky issues (how to preserve coherence at body temperature, etc). MPI's stance is that *if* psi is like entanglement, this entanglement might be **abstract** perhaps a correlation of meaning across minds and detectors – not necessarily literal quantum entanglement of particles. In this sense, MPI is **compatible** with Orch-OR in spirit (both say classical causality is not the whole story), but **neutral** on its specifics. MPI would neither refute nor confirm that microtubule collapses cause consciousness; it would say, "that's an interesting substrate hypothesis, but even if true, it doesn't automatically explain macro-scale psi correlations." For instance, even if Orch-OR is correct that consciousness arises from quantum state reductions, one would still need MPI's framework (or something like it) to understand how a person's inner state could correlate with an external event (like influencing an REG machine or having a telepathic hit) *without* sending signals. Indeed, MPI might view a human performing psychokinesis in an Orch-OR world as: the person's quantum brain events become entangled with the device's state – but any attempt to exploit that entanglement as a signal fails (NT axiom holds), consistent with both frameworks.

Notably, both MPI and Orch-OR have a **Platonic tinge**: Penrose talks of Platonic mathematical truths embedded in fundamental spacetime guiding collapse outcomes en.wikipedia.org, whereas MPI speaks of "pragmatic information" and meaningful correlations shaping reality. In MPI, it's almost as if meaningful *information* is a cau

agent (or at least a selector of outcomes) – a concept not unlike a Platonic form asserting itself. However, MPI stops short of metaphysics about absolute truth or geometry; its “meaning” is contextual, tied to the observers in the system. Penrose’s Platonic influence is more absolute (mathematical truth influencing physical events). This difference highlights that MPI is **operational and phenomenological** (describe the patterns and constraints of psi we can observe), whereas Orch-OR is **ontological** (describe the underlying units of reality that give rise to mind).

In conclusion, MPI is **largely agnostic** to Orch-OR: one could potentially integrate two by saying consciousness arises from Orch-OR quantum processes, and when organized in a certain way (a closed socio-psychological system), those conscious processes can engage in entanglement-like correlations described by MPI. But one could just as well imagine MPI working with a classical brain (no special quantum brain effects needed) – as long as the system’s **information structure** permits nonlocal correlations. In fact, MPI’s successful predictions of decline and displacement do not require accepting any of Orch-OR’s controversial points (like microtubule coherence). This suggests MPI is a “*higher-level*” theory that could be true regardless of which “lower-level” theory of consciousness (Orch-OR or otherwise) is correct.

Michael Levin’s Platonic “Mind Everywhere” vs. MPI

A very different approach to the mind-matter question comes from biologist and computer scientist **Michael Levin**, who has championed a framework in which *intelligence and mind-like properties emerge in many systems*, not just human brains. Levin’s work spans regenerative biology (how cells cooperate to rebuild organs) to unconventional computation. He provocatively suggests that even simple, classical systems can exhibit *basal cognition* – goal-directed, problem-solving behavior – with any quantum magic or even without any neural tissue. For example, Levin and colleagues demonstrated that a deterministic **sorting algorithm** (a few lines of code) can be reinterpreted as a collection of “agent” elements that cooperatively solve problems and even exhibit preferences or “*wants*,” if you look at it from the right

perspective. In one study, they modified a sorting program so that each number in the list acted autonomously with simple rules, and they observed the system spontaneously finding creative solutions and sub-goals when obstacles were introduced. The implication is that even algorithms – which we normally think of as doing exactly what they are programmed to do – can surprise us with emergent “intelligence” when analyzed at the system level. Levin argues this means our notion of cognition should not be restricted to brains; *mind is a continuum* that appears in degrees across many substrates.

Crucially, Levin invokes a kind of **Platonic realm of forms or truths**. He speculates that there is a “space of possible forms and goals” – akin to how mathematicians consider numbers or geometries to exist abstractly – and that living organisms (or even algorithms) can “tune into” these patterns. For instance, a developing embryo might achieve a correct anatomical structure by exploiting inherent geometric truths (like gradients or symmetry principles) that pre-exist as potential patterns. Levin’s Platonic view is that *these patterns don’t require quantum physics or new forces*; they’re available in the classical world as higher-order organizational principles. In his framework, a **sufficiently complex classical system can latch onto this space of forms** and display cognitive behaviors – effectively, *“minds” can ingress into deterministic systems as emergent properties*. It’s a bold reconciliation of emergence with a hint of universality: even weather systems or electrical circuits might have rudimentary “mind” if organized properly, and we shouldn’t dismiss that possibility a priori [thoughtforms](http://thoughtforms.life) thoughtforms.life. Levin often says we need humility in recognizing intelligence in unfamiliar guises thoughtforms.life thoughtforms.life.

How does MPI relate to Levin’s ideas? On one hand, both MPI and Levin’s framework emphasize **emergent organization** and do not require quantum mechanisms. MPI’s entanglement correlations occur in *self-organizing systems that exchange meaningful information*; Levin’s “mind everywhere” suggests *self-organizing systems can exhibit agency and purpose* if we interpret them correctly. Both views challenge a strict reductionism that would deny any possibility of mind or psi in simple systems. In fact,

Levin's work might provide a kind of conceptual bridge: if even a classical algorithm can show a glimmer of "preference" or learning, then perhaps the gap to something like psi (which implies a coordination between mind and environment) isn't so large. We could imagine that once systems reach a certain level of closed-loop complexity not only do they behave intelligently, they might also develop **entangled correlations** with other parts of the system (like environment or other agents), which is essential MPI's territory.

However, there are differences in emphasis. Levin's framework is about **cognition as an intrinsic aspect of matter/organization** – it's more *panpsychist* or pan-protocognitive, suggesting a continuum of mind. MPI doesn't explicitly claim that everything is minded, only that if a system becomes organizationally closed and meaningful information is shared, psi can result. MPI is silent on whether a simple algorithm "wants" something; it would only comment if that algorithm (plus an observer, perhaps) formed an entangled system showing psi. That said, one could speculate: a system that *does* have emergent goals (in Levin's sense) might be exactly the kind of system where MPI effects become possible, because goal-directed behavior implies feedback, interpretation, and perhaps shared meaning. Levin speaks of **degrees of agency** even in non-biological systems – MPI could add that with higher agency and self-reference, the system might exhibit nonlocal correlations (psi) as another facet of its holistic behavior.

Another angle: Levin's Platonic space of forms is reminiscent of the idea that certain outcomes are "selected" because they fit a broader pattern or truth. In MPI, there's an analogous notion that outcomes in a psi experiment are not random but not straightforwardly caused either – they seem to be selected based on meaningful correspondence or the experimenter/subject's expectations (without their conscious knowledge). For example, if a person emotionally needs a "meaningful coincidence," psi might provide one, but not through direct cause – rather through a coincidence that *makes sense* to them (like an RNG spiking exactly when they have a thought, etc). This hints at some ordering principle beyond chance, which one could loosely

compare to Levin's space of latent goals or forms. The key difference: Levin's ideas remain **fully within classical causality** (just complex feedback loops), whereas MPI's psi explicitly **violates causal closure** (events correlate without forces). Levin's work would likely classify psi results as either fraud or some unknown classical feedback. MPI would insist they are real but non-classical. Are these views incompatible? No necessarily – Levin might not have focused on psi, but if confronted, he might consider whether his “space of forms” could allow meaningful coincidences that are not locally caused. Since he already entertains non-obvious emergent phenomena, he might be open to MPI's notion that some patterns manifest acausally as long as they don't all involve information transfer (which preserves overall physical law).

In summary, MPI appears **broadly compatible** with Levin's framework in that both highlight emergent, system-level phenomena and don't invoke mystical physics. MPI could be seen as *complementing* Levin by addressing phenomena (psi) that Levin's theory doesn't yet explain – giving a mechanism (entanglement correlation) by which those ubiquitous “minds” could sometimes know or affect things beyond their apparent reach. On the other hand, if one were skeptical, one might say Levin's work attempts to explain mysteries (like regeneration, unconventional computing) *without* resorting to anything paranormal, whereas MPI unabashedly embraces the paranormal (albeit in a formal way). Levin explicitly states his framework “does not require quantum events” and contrasts it with quantum-centric ideas. MPI likewise doesn't require quantum physics, but it does use quantum analogies. So one could argue MPI and Levin share a *philosophical openness*: mind and meaningful connections pervade nature more than we assume. But they diverge in testable claims: MPI predicts declared effects and psi hits; Levin's predictions are more about finding intelligence in worn-out robots, or algorithms. Time will tell if these threads converge – for instance, if a future experiment shows a simple AI algorithm demonstrating psi-like coincidences, that would unite Levin's and Lucadou's worlds in a fascinating way.

Having situated MPI relative to Orch-OR and Levin's models, we now turn to apply MPI in depth to specific discussions and case studies. The next sections integrate MPI

with previous explorations of psi's elusiveness, a proposed mass experiment using blockchain, and the cultural diffusion of the "sacred" into mainstream – showing how MPI can shed new light on each.

Why Psi Is So Hard to Prove: An MPI Perspective

For anyone who has tried to scientifically validate psi, the frustration is palpable: promising results often **evaporate under replication**, effect sizes wane over time, and skepticism remains high. In an earlier piece titled "[*Why Psi is So Hard to Prove*](#)," this paradox was explored in detail – noting historical examples like the decline of ESP card guessing successes and the mixed outcomes of remote viewing programs. **MPI offers a principled explanation for this elusiveness** that ties together many of those observations.

First and foremost, the **NT axiom** of MPI directly addresses why psi phenomena cannot be pinned down as robust, communicable signals. If any psi effect becomes reliable – say, a person consistently scores 100% on telepathy tests – one could start using that as a telephone to send messages. According to MPI, **nature disallows this**. As soon as conditions shift from a spontaneous, meaningful context to an attempt at *controlled transmission*, the entanglement correlation that underlies psi collapses. This is not just a theoretical conjecture; it maps onto decades of empirical lore in parapsychology. Many gifted subjects in early research performed amazingly in informal tests but lost their abilities in formal lab trials or over time as pressure mounted. Under MPI, this is expected: the initial tests likely occurred in a more relaxed, "*endo-system*" state – the subject was absorbed in the task and not overly observed or self-conscious, allowing entanglement correlations to flourish. But once the goal became "prove to the scientific world you have ability X," the subject effectively left the "*heaven of the endo-system*", and the magic vanished. Anecdotally, many psychics say they can't perform on demand or under skeptics' gaze; MPI would say the **organizational closure** and subconscious trust that sustained the psi link is broken in those conditions. The "trickster" nature of psi – where it seems to play hide-and-seek – is a direct consequence of the NT axiom acting as a natural limiter.

Secondly, MPI formalizes the **decline effect**, which was noted in "[*Why Psi is So Hard to Prove*](#)" as a common pattern. If a person or experiment hits above chance initially, subsequent trials often show diminishing returns, sometimes sliding back to chance outcomes. In MPI, recall that pragmatic information has a novelty component (E) and

a confirmation component (B). Early trials in a psi experiment carry a lot of *novelty* - the situation is uncertain, the participants are exploring their own abilities, and unconsciously everyone is wondering “Is something happening here?” This high E (novelty) allows significant pragmatic information exchange: surprising results can occur. But with repeated trials, **novelty inevitably decreases**. The participants and experimenters develop a strong expectation (confirmation) of what the result should be (perhaps expecting an effect or, conversely, expecting regression to the mean).

According to MPI, this very increase in B (confirmation) at the expense of E (novelty) will diminish I (pragmatic info) if the product $B \times E$ remains constrained. Essentially the system “settles” and stops producing anomalies. The MPI model even suggests mathematically that effect size might drop proportional to $1/\sqrt{n}$ or similar with number of trials, which is consistent with meta-analytic data. The *PEAR experiments* are a prime example: the first 1000 trials showed a noticeable PK deviation; tens of thousands of trials later, the average moved much closer to null, as if the system ran out of juice. Interestingly, in some cases after a decline, researchers have seen a “revival” of effects when something changed (a new operator, a pause in the experiment, etc.), injecting novelty again. MPI predicts such tantalizing revivals should occur – a kind of psi oscillation – but ultimately if you keep pushing, the outcome stabilizes at chance (the system equilibrates to no usable signal).

Another key concept making psi hard to prove is **displacement or evasion**. As detailed earlier, if you try too precisely to capture psi in one channel, the correlation might **shift to another channel** or become distributed in such a way that it’s hard to detect any one measure. In practical terms, this means experiments often end with ambiguous results: maybe the primary outcome is null, but some odd correlation turns up in exploratory analysis – a hint that “something” happened, just not what was expected. Skeptics chalk this up to data mining, but MPI suggests it could be the psi effect “escaping” the trap set for it, appearing where nobody set a prior hypothesis (hence it can’t be used as proof, preserving NT). This again has been seen historically. J. B. Rhine’s high-scoring card-guessers would suddenly start missing targets but then report “screen memories” or subtle cues that related to targets in other ways. Or an

experiment might find no telepathy effect in the target pictures, but notice the senders and receivers had oddly synchronized physiology during the trials – as if the connection manifested in a different metric. MPI would encourage researchers to take such side-phenomena seriously as part of the overall entangled system response, rather than dismissing them entirely. It also advises that **strict replication protocols** while necessary for science, are ironically the bane of psi – because replication squeezes out novelty by design. Psi thrives on spontaneity and meaningful context, which standardized methods tend to remove. This is why anecdotally, psi often appears in **one-off “peak” events** (a dramatic premonition, a poltergeist outbreak) associated with emotional significance, but these cannot be recreated at will.

From the MPI perspective, then, **psi is hard to prove by design**. It's not simply our insufficient methods or lack of data; it's that psi's very existence is tied to conditions that are antithetical to the proof-oriented mindset. Proof demands consistency, isolating variables, and removing ambiguity. Psi demands meaning, holism, and a bit of mystery (ambiguity) to operate. If you remove all ambiguity – say, a perfectly controlled test – MPI implies the psi effect will disappear, becoming a null result that proves nothing (or at most, manifests as a tiny statistical deviation that leaves room for doubt). This doesn't mean we can never study psi scientifically; it means we must get clever about **creating experimental contexts that satisfy psi's need for autonomy while still gathering evidence**. Lucadou has suggested approaches like using **Correlation Matrix Method** experiments that analyze many interrelated variables without fixating on one outcome signal, thus attempting to circumvent the NT axiom by “sneaking up” on psi in a multivariate way. Those are advanced strategies beyond our scope here, but it's worth noting that MPI not only diagnoses the problem, it hints at solutions: *don't try to grab psi too tightly; let it manifest in a rich system and observe it indirectly*.

In summary, MPI accounts for psi's elusiveness and decline by showing that **strong repeatable psi** is a self-cancelling proposition. The very act of making psi repeatable bleeds it of the conditions that produce it. What's left are small effects and

frustratingly inconsistent outcomes – which is exactly the landscape we see in parapsychology (highly significant meta-analyses combined with difficulty reproducing any single experiment on demand). This perspective can be sobering – suggests there may never be a “smoking gun” proof that convinces all skeptics – but it’s also empowering in a way. It says that *meaningful experiences* of psi (often person unique, context-laden) are valid in their own right and not invalidated by the inability to summon them at will. It also reframes the task: perhaps we should stop trying to **prove** psi as if it were a binary and instead **understand** psi as a complex, delicate natural phenomenon with its own lawful limits.

Next, we’ll examine a bold attempt to “crack” psi’s mystery with modern technology a massive online experiment – and analyze it through MPI’s discerning lens.

The Greatest PSI Experiment Ever? MPI’s Analysis of a Massive Social Experiment

Social Remote Viewing

Your dedicated platform for practicing, sharing, and studying Remote Viewing

In “[*The Greatest PSI Experiment Ever*](#),” the concept of a global, blockchain-based remote viewing experiment was proposed as a way to finally produce unequivocal

evidence for psi. The idea is ambitious and exciting: leverage the power of the internet and crowdsourcing to gather thousands of participants, use **blockchain** timestamps to ensure targets and responses are securely blinded and logged, and analyze data in real time with total transparency. The experiment is essentially an array of psi games – from classic ESP card tests to live remote viewing to precognitive predictions – gamified to attract large participation and fortified with technology to preclude cheating or selective reporting. For example, one game might have people all over the world guess a hidden image (remote viewing), with an AI scoring the similarity of their drawings to the actual target once revealed. Another might attempt mass precognition via “associative remote viewing” on future events like sports outcomes, using the blockchain to lock in predictions ahead of time. The promise is that with **enough data** (**Big Data meets Psi**), even a weak effect could be detected at astronomical significance levels, and the blockchain ensures no data tampering or p-hacking. It’s essentially throwing the latest tech at an age-old problem, hoping to break the stalemate that has left psi research in a gray zone.

From an MPI standpoint, this grand experiment has both **strengths and potential blind spots**. Let’s examine them one by one:

- **Strength: Scale and Engagement.** One thing MPI does not forbid is accumulating lots of trials. While an overly rigid protocol can dampen effects, having many participants who are *intrinsically motivated* (even if partly by fun or rewards) can maintain a level of novelty and autonomy in the system. A global online game creates a kind of **socio-psychological mega-system**, where each participant’s experience is unique (introducing variability and novelty) yet all are loosely coupled through the platform. This has the potential to form a large entangled network, especially if participants interact or compare scores – a **community of observers** entwined with the targets and outcomes. MPI would actually encourage such richness, as opposed to a dozen people in a lab doing the same task for weeks. The *engagement* factor (leaderboards, curiosity, perhaps even mild competition) can also sustain participants’ attention in a way that fosters the

“subconsciously fascinating” quality MPI says is needed for psi to manifest. In MPI terms, the gadgetry of the blockchain and the slick interface might serve as a “pseudo-machine” that participants *believe* in just enough to generate entanglement correlations, even though from outside it’s just a randomizer with a database. If people are excited and partly suspending disbelief (“maybe I *can* remote view this target!”), they are effectively entering that endo-perspective where psi can operate. The large N of trials then helps tease out any signal from the noise.

- **Strength: Transparency and No Normal Cheating.** The use of blockchain for target selection and data logging is meant to answer normal criticisms (fraud, optional stopping, file-drawer effects). From MPI’s viewpoint, eliminating normal information leakages and fraud is necessary – psi effects should be studied only when normal causality is tightly sealed off, otherwise one can never be sure if a result was due to a stray cue. The blockchain ensures targets aren’t known until after responses are collected, fulfilling the “**quantum observation**” analogy of psi experiments (no normal info can contaminate). This basically creates a clean canvas on which any correlation truly must be psi (if it’s there). MPI would approve of such rigor; indeed, Lucadou often collaborated in designing high-integrity experiments. But MPI would caution: the more you “secure” the protocol, the more you risk squeezing out the psi, because you might also be squeezing out participant flexibility or subconscious leeway. However, the innovation here is that participants themselves might still feel at ease – they just play a game – while the *backend* is what’s rigid. That could be the best of both worlds: **endo-level freedom, exo-level rigor**. If done perfectly, this maximizes the chance that any detected effect is real.
- **Blind Spot: The NT Axiom Strikes Back.** The very **purpose** of the mega-experiment is to *demonstrate psi to the world with unprecedented certainty*. From an MPI lens, this raises a red flag: it is exactly the kind of overt *use of psi as a signal* that NT says will be self-defeating. In other words, if the universe abides by the NT axiom, then an experiment explicitly designed to shout “Psi is real!” from the

rooftops might be paradoxically doomed to produce null results (or confusing ones). The more public and high-stakes the proof, the more likely the entanglement will collapse under that weight. One might recall historic example the Stanford “remote viewing” project yielded intriguing data when it was secret private, but as soon as it went public and faced scrutiny, results became inconsistent. Similarly, high-profile tests of famed psychics (like Uri Geller) often failed spectacularly on live TV or in tightly controlled settings, whereas in informal demos they succeeded. The proposed blockchain experiment would, in effect, put psi on stage before a global audience – a kind of continuous live demonstration. MPI would predict *either* no significant effects will emerge (the rate stubbornly stays at 25% in the ESP card game, for instance), *or* if an effect does start to emerge, something will **shift in the system to undermine it** (e.g. participants lose interest over time, or a software bug, or the effect moves into a variable that isn’t being monitored). In MPI terms, the experiment might inadvertently create a huge **exo-perspective** (because of the public scrutiny) rather than an optimal endo-perspective for participants. Everyone knows everything is tracked and visible; that might create a subconscious sense of being observed or judged that dampens psi-conducive mindset.

- **Blind Spot: Decline and “Gaming the Game.”** Let’s imagine the experiment launches and initially finds a small but genuine psi effect – say the remote viewing game has a hit rate of 27% instead of 25%, with $p < 0.001$ after a million trials. Excitement ensues. According to MPI, this very success could sow the seeds of decline. As news spreads that the crowd is achieving above chance, participant motivation might change: skeptics might join to “balance it out” or believers might push too hard to keep the streak going. The system’s **psychological variables** would change once it’s half-proven. Indeed, Lucadou noted that the mere attempt to *replicate* a success in psi often triggers decline. In a continuous experiment, replication demand is effectively in real-time – every new batch of data is a replication. So one might see a strong early result fade over weeks as the novelty wears off and people start second-guessing. Additionally, if there are

monetary rewards or leaderboards (as mentioned, to incentivize engagement), must consider MPI's point about the "paradise of unintentional, holistic" vs intentional use. With prizes on the line, participants might start employing more analytical thinking or even collusion to win, which would kill any psi that relies on spontaneity. Or they might simply over-focus, losing the playful mindset that might have enabled micro-psi to begin with. *Gamification is a double-edged sword*: it can make participation fun (good for autonomy) but also introduce conscious striving for reward (bad for psi, which is famously shy under competitive or ego-driven conditions).

- **Possible Success (within Limits)**: Is there a way the experiment *might* succeed under MPI assumptions? MPI would allow that **small, distributed correlations** could be found, especially if the analysis is clever. For instance, maybe no individual has significant psi, but an aggregated result across thousands shows tiny deviation. This might slip under the NT-axiom radar because no single person or trial is "using psi;" it only emerges statistically. MPI's formalism would call it a nonlocal correlation that only becomes apparent after the fact (after many trials, analyzed retrospectively, not used to predict a single event in real time). Importantly, that satisfies NT because you're not actually transferring usable info in any given instance – you only see the anomalous info when averaging. In that scenario, the experiment might "work" in the sense of providing strong evidence to scientists (via p-values), yet ironically it still wouldn't let anyone *win the lottery reliably* or *know a target with certainty*. MPI would smile and say: "See, psi is real but still obeyed the rules: you got your correlation, but you couldn't *do* anything with it in advance." If the organizers of the experiment frame success in that way, it aligns with MPI: success = a significant correlation, not an actionable signal. If however they aim for a scenario where thousands of people get consistently rich precognizing stocks (for example), MPI would predict failure or chaos.

In evaluating the Social Remote Viewing experiment, MPI would **critique its blind faith in brute-force empiricism**. Yes, more data can reveal smaller effects, but only

the effect exists in the first place and *persists* across that data collection. MPI warns that psi effects might actually **mutate or vanish** under such continuous observation possible outcome is that the experiment runs for months, finds nothing conclusive, and skeptics declare victory (“told you so”), not realizing that a null result is exactly what an entrenched psi phenomenon would look like if NT-axiom holds. To make progress, MPI might advise *building conditions into the experiment that maximize meaningful engagement and minimize performance pressure*. For instance, rather than emphasizing “Help prove psi to the world!”, the experiment could be presented simply as a fun challenge (“Test your intuition, see how you rank”) so that participants are not *too* outcome-driven. It could also incorporate **periodic changes** or *new tasks* introduced over time to inject novelty when a decline is detected (like rotating target types or adding narrative elements to keep excitement up). Essentially, treat the experiment itself as *adaptive*: if the effect wanes, adjust something (without violating protocols) to refresh interest.

MPI might also suggest mining the data for **secondary correlations** (displacement effects). Maybe direct hit rates on the target go to chance, but perhaps participants unknowingly start describing the next target, or their biosensors (if any are used) signal in interesting ways. The blockchain experiment, if instrumented broadly, could catch these unexpected outcomes. Lucadou’s own experiments found that when participants couldn’t influence one random generator, sometimes an *unused second generator* picked up a correlation – as if psi displaced to the only place it wasn’t being scored. A savvy analysis in the greatest experiment might look for analogous things.

In conclusion, the **Social RV blockchain experiment** is a bold and commendable effort to bring psi research into the 21st century. MPI would view it as a grand test not just of psi, but of MPI itself: will the psi effects, if present, obey the two “laws” (nonlocal but elusive)? If the experiment finds a real effect but only as a subtle correlation (not usable info), it will strongly support MPI’s paradigm on a massive scale. If it finds absolutely nothing, one could interpret that through MPI as well (perhaps the experimental context was too public/utilitarian). And if it unexpectedly found *clear*,

repeatable psi signals, MPI would be in trouble – but based on all we’ve discussed, the outcome would indeed be *the greatest* upset to MPI’s model.

Next, we turn to a different domain: not experiments, but the cultural journey of psi and esoteric ideas – how they enter mainstream awareness and what MPI might say about the illusions and insights that emerge in that process.

When the Sacred Goes Mainstream: MPI on Esoteric Truths and Mass Media

Mystical and psychic phenomena have often been regarded as “sacred” – in the sense of hidden, special, or accessible only under certain conditions (spiritual practice, initiation, etc.). However, in modern times, we’ve seen a **flood of esoteric ideas into the mainstream**: meditation and chakra healing in self-help books, psychics on TV, spoon-benders on YouTube, and so on. The article “[*When the Sacred Goes Mainstream: Wisdom, Delusion, and the Future of Esoteric Truths*](#)” delved into the double-edged sword of this diffusion. On one hand, greater openness can democratize knowledge and inspire many. On the other hand, it can lead to **dilution, exploitation, and fakery** – turning subtle truths into oversimplified slogans or outright scams. How might MPI principles help us navigate this landscape, especially concerning claims of psi or miracles that enter pop culture?

First, MPI’s concept of **pseudo-signals and pseudo-machines** is directly relevant to the proliferation of dubious devices and demonstrations in the mainstream. A *pseudo-signal*, recall, is an **internal impression of a psi signal** that cannot actually be used externally. Many public demonstrations of psychic ability likely involve people mistaking a pseudo-signal for a real one – or worse, deliberately faking a signal. For example, initial believers’ enthusiasm in a psi effect may possibly stem from genuine *pseudo-signal experiences* – there might really be a legitimate experience of something paranormal happening. But the moment an attempt is made to shift the signal to the **mass-market as a guaranteed skill** without understanding NT, it may devolve into self-deception or fraud. MPI would not be surprised: any promise of a **reliable, on-demand psi ability for sale** is almost certainly violating the NT axiom, meaning if it ever worked authentically in a few instances, it will stop working once commercialized. To fill the gap, people may resort to **tricks** – and historically we see

exactly that. The 19th-century Spiritualist movement began with sincere belief in spirit contact but soon spawned many fraudulent mediums who used stage magic to produce phenomena when the real ones didn't show up on cue. MPI's two laws predict that genuine psi phenomena *cannot* be guaranteed or produced as spectacle reliably any scene that demands constant miracles (weekly séances, daily fortune-telling for pay, etc.) will inevitably encourage **illusion** to meet the demand when reality doesn't oblige.

Dilution of ideas is another theme: profound concepts get dumbed down. The Hermetic teaching "Mind is the underlying reality" turned into the pop mantra "Your thoughts create your reality," famously marketed in *The Secret*. While MPI is a technical theory and doesn't dictate self-help, it implicitly warns against **context collapse**. A principle like "mind influences matter" in a magical worldview was always accompanied by caveats – it required spiritual purity, or ritual, or divine grace. Stripped of context, it becomes "think positive and you'll get rich," which is misleading and can be cruel (e.g. blaming patients for not visualizing health enough). MPI would say: If mind truly does influence matter, it's in the form of *non-causal correlations* that you can't simply will into being for egoic ends. Oversimplifying that as a cartoon version ("I can manifest a parking spot because quantum physics!") is asking for disappointment – either nothing happens and one loses faith, or one attributes normal coincidences to an ability one doesn't actually have control over, which is **magical thinking** of a problematic sort. MPI celebrates *meaningful coincidences*, yes, but it also sets strict limits: you cannot summon them like a genie. The mainstream new-age rhetoric often skips those limits, leading people to either delude themselves or feel disillusioned. As *When the Sacred Goes Mainstream* noted, "*a nuanced metaphysical principle turned into materialistic wishful thinking*", which helps no one in the long run.

An important concept MPI adds is the idea of maintaining **organizational closure** and **context** for psi or spiritual knowledge to function. Traditional esoteric schools protected certain teachings, not out of elitism per se, but perhaps intuitively knowing

that misuse or misunderstanding could occur without proper foundation. MPI can rationalize that by saying the *psychological environment* needed for these truths (say, disciplined meditation practice, ethical grounding, a master-student trust) forms a kind of closed system where entanglement correlations (insights, perhaps small miracles or siddhis) can happen. Throw the same practice into a commercial works with random attendees, and the system isn't closed or cohesive – it's full of external motives and mixed intentions. The “signal” (truth) gets lost or distorted. The *ancien* weren't *wrong to be careful*, as the article says. MPI would add: once the exo-view (outsider perspective) intrudes heavily – e.g. mass media spotlight – the delicate enc conditions break. For example, consider the difference between a shaman's healing ritual within a tribe (everyone shares belief, context – a closed system of meaning) versus the same shaman demonstrating in a lab while being filmed for TV (now it's open system, half the people are skeptics, cameras whirring – meaning is not shared). MPI predicts the shaman's success will drop dramatically in the latter scenario. This often happened when *National Geographic* or others tested healers on camera: results were equivocal, unlike testimonials in their communities. It's a vivid illustration of **contextual collapse** undermining psi.

MPI also sheds light on the attraction of “stage magic style” claims and why skepticism is healthy when the sacred goes mainstream. If someone on a Netflix show claims they can reliably read minds or summon UFOs at will, MPI says be wary – because if it's packaged that neatly, it's likely **either false or not purely psi**. Perhaps it's clever editing or trickery because *if it were real and that overt, it would violate NT* (either NT is wrong, which would revolutionize science, or more plausibly, the claim is suspect). That doesn't mean all publicized phenomena are fake, but MPI biases us toward assuming subtlety: real psi might still appear in mainstream contexts, but only in ambiguous ways. For instance, a reality show about mediums might have some real hits, but also lots of misses and general statements – leaving wiggle room. That ambiguity *fits* MPI (no clear info transfer, just tantalizing correlations). When mainstream presentations lack any ambiguity (100% hit rate, all skeptics silenced), experience shows it's usually a trick.

Finally, consider **siddhis** (psychic powers in spiritual traditions) and how enlightened masters treated them. As noted in *When the Sacred Goes Mainstream*, masters like Sri Ramana Maharshi and Nisargadatta Maharaj warned against chasing siddhis. They regarded them as by-products at best, illusions at worst, that could derail one's spiritual progress through ego-inflation. MPI provides a rationale: actively developing siddhis means *trying to wield psi intentionally*, which we know tends to backfire (at least spiritually, it can entangle one in worldly craving, and practically, it will stop working consistently). The masters likely observed that students who got caught up in psychic experiences lost sight of the ultimate goal (self-realization) and often fell into error, sometimes even deceiving themselves or others about their attainments. This echoes MPI's emphasis that **meaning and self-growth** should perhaps be the focus, not using psi for gain. When the sacred goes mainstream, the focus often shifts to the *wow factor* (cool powers, secrets to get what you want). MPI and the sages align in implying that this is a sidetrack. The real "sacred" might be the *transformation of consciousness*, with psi phenomena only as ephemeral side-effects or symbolic messages. If we bring esoteric wisdom to the public, MPI would encourage doing so in a way that emphasizes **context, ethics, and the inherent uncertainty** of these realms. For example, teaching meditation widely is great (it's been mainstreamed fairly successfully) because it's framed as improving wellbeing and insight – any mystical experiences are bonus and not guaranteed. In contrast, teaching "telekinesis for beginners in 10 easy steps" would be setting people up for either disillusionment or delusion.

In summary, MPI frames the mainstreaming of the sacred as a process fraught with **loss of systemic integrity**: the original closed contexts that gave rise to genuine psi and profound insight are broken open, often yielding either empty hype or outright deception in their place. Yet, MPI wouldn't say to hide everything – rather, to **transmit carefully**. Just as one must design psi experiments that respect psi's constraints, one must introduce esoteric knowledge in ways that respect its depth. Maintaining some *mystery and humility* might actually be necessary for the knowledge to retain its power (and truthfulness). The more our culture demands entertainment and instant results, the more likely we are to encounter "pseudo-truths" – ideas or devices that look like

the real thing but lack the substance, much as MPI's pseudo-machines mimic effects without real psi.

Finally, let's explore how MPI's lens extends to the highest reaches of inner exploration – enlightenment and nondual consciousness – and then apply it across a wide range of anomalous phenomena in a taxonomy that separates the meaningful from the mythical.

Enlightenment Experiences and the Veil of Ignorance: Is MPI Compatible with Nonduality?

In “[*Academic Research on Enlightenment and Persistent Nondual States*](#)” and “[*Enlightenment, the Veil of Ignorance, and the Nature of Reality*](#),” the focus shifts to extraordinary states of consciousness – often described in terms of **self-transcendence, unity, and nonduality**. These are states where the usual separation between self and world, or observer and observed, dissolves, yielding a profound sense of wholeness or even oneness with all that is. Such experiences are typically accompanied by a collapse of conceptual thinking and a direct, ineffable knowing. A question arises: how might MPI, a model built to explain psi correlations, intersect with models of consciousness that are **self-transcending and nondual**? Can entanglement correlations shed light on enlightenment, or vice versa?

At first glance, MPI and classical enlightenment models seem to run on different tracks. MPI is about interactions in systems; enlightenment is about the *substratum* awareness itself. However, there are intriguing points of resonance. Consider what happens in a **nondual experience**: the boundary between the individual (the “organizationally closed system” of the person) and the environment seems to melt away. In Advaita Vedanta terms, the jiva (individual soul) realizes it is Brahman (the All) – the ultimate closed system containing everything. In Buddhist terms, the subject-object duality is seen as an illusion (a play of emptiness). If one were to express this in MPI's language, you might say that in enlightenment the person's **exoteric**

boundary dissolves; they no longer see themselves as separate from the rest of the system. Therefore, the entire universe (or whatever is in conscious awareness) effectively becomes **one giant organizationally closed system** from the vantage point of that consciousness. And interestingly, MPI says entanglement correlations occur *within* an organizationally closed system. If one's sense of self expands to everything then in principle **everything is entangled with everything** (since it's all "within" the One Self). This is a bit metaphysical, but it suggests that in nondual awareness, psi phenomena might be perceived not as anomalies but as natural, because the person no longer subconsciously rejects information from "out there" – there is no "out there." Mystics often claim that in enlightened states, synchronicities and intuitive insight become more common, as if reality is more fluid or responsive to mind. MPI would be sympathetic to that possibility: the usual psychological barriers that keep the psychological system limited might relax, allowing more entanglement correlations to show through. However, the enlightened being typically has **no personal desire to exploit them**, which fits perfectly with NT axiom compliance. They see it all as one play of consciousness, so who is there to send a signal to whom? Indeed, many gurus say siddhis can manifest spontaneously around an enlightened master, but the master often ignores them as trivial or potential distractions. From an MPI perspective, the ideal: the environment around such a person might be rife with **pragmatic information exchange** (meaningful coincidences, healings, etc.), precisely because the master has zero intent to use them for gain – they remain in the "*paradise of unintentionality*", keeping the entanglement intact. The moment a disciple says "teach me that power," the master often responds "let it go; focus on higher truth," implicitly knowing (perhaps intuitively) that grasping at the power will drive it away or lead off course.

Now, **symbolic breakdown**: Enlightenment is often described as going beyond language, beyond concepts – a state where the **symbolic filters drop** and reality is experienced directly. This resonates with MPI's idea of complementarity between structure and function. Our normal consciousness uses a *structure* of concepts, labels and narratives (in MPI terms, a certain measurement framework) to function in daily

life. Enlightenment might be seen as a flip to the complementary mode: pure *function* or pure being without imposing structure. In that state, one might be open to vastly more “pragmatic information” because nothing is being filtered out or narrowly categorized. Perhaps this is why enlightened reports include statements like “all is self, all is consciousness” – they aren’t focusing on separate pieces of information, they’re experiencing the holistic *meaning* of existence in one gulp. It’s like an ultimate entanglement-perception, where everything correlates with everything because it’s one. Hans Primas, cited in the MPI text, talked about “endo-descriptions” of systems where one describes from *inside the ontic state*, which is inaccessible experimentally but not meaningless. Enlightenment could be the mind’s recognition of that *endo-perspective of reality* – seeing the whole from within, rather than as an outside observer parsing parts. That tracks with mystical language: “*the veil of ignorance*” (the illusion of separateness) drops, and one realizes the cosmos as self.

If that is so, MPI would say enlightenment is like achieving perfect organizational closure (nothing is outside the self-system anymore) and maximum autonomy (freed from external control, because there is no external). Interestingly, MPI’s equation $I \times A$ suggests that if autonomy (A) is maximal (like complete freedom of consciousness), reliability (R) might be minimal for external observers. This could translate to enlightened beings appearing a bit inscrutable or not performing repeatable “tricks” for scientists. Many enlightened figures do not readily demonstrate psi under lab conditions – not because they can’t, but perhaps because the state doesn’t lend itself to being a lab rat. They may have a different relationship with reality that doesn’t always translate into the kind of repeatable effect science wants, again due to NT-like reasons (the phenomenon is holistic and context-dependent).

Academic research on enlightenment (as summarized in that article) notes things like changes in brain networks (e.g. decreased default-mode network activity indicating loss of self-referential thinking). That is essentially the brain correlates of dropping symbolic, egoic processing. In MPI terms, maybe the “measurement function” in the brain that usually fixes reality into separate objects is toned down, allowing more

nonlocal coordination within the brain and perhaps with the environment. It's speculative but not far-fetched to imagine that a brain in nondual awareness might be more hospitable to psi: indeed, some studies of meditators show they score better in psi tasks than non-meditators, although results are not uniform. If nonduality is persistent, the person might live in a kind of sustained entangled state with surroundings – what Jung and Pauli called *synchronicity* might become almost ordinary.

However, MPI would also counsel **caution** here. Just because someone has nondual insight doesn't mean everything they experience is psi or objectively real in a conventional sense. Enlightenment experiences are primarily about the nature of consciousness and self; they can be **self-validating** but hard to express. If someone tries to pull an "NT-violating" stunt like, "Because I am one with all, tomorrow I will levitate in front of everyone," MPI says that's likely to fail or be a mix of illusion, because now they're treating unity as a *signal or force to use*, rather than a state of being. Historically, genuine spiritual masters rarely made such flashy displays, and if miracles occurred around them, they were often spontaneous or for a devotee's benefit, not paraded as proof. This aligns with MPI: any conscious attempt to use oneness for egoic demonstration would ironically reinforce duality (the ego acting) and snap the state or at least void the correlation.

One could also ask: Does MPI's **meaning-based causality** jibe with the idea that ultimate reality is *beyond meaning* (as some nondual teachings suggest)? Enlightenment is often described as seeing the emptiness or inherent lack of fixed meaning in phenomena, with meaning being a mind-imposed layer. Yet at the same time, mystical experiences are deeply meaningful in a felt sense (everything is seen as perfect, or love, or divine). MPI's notion of pragmatic information is not about semantic content as language, but about the significance an outcome has for the system. In a nondual state, every occurrence might be equally significant (or insignificant) since all is self – a sea of zero-point of pragmatic information where R and A are in balance with B and E in a continuous flow. That gets abstract, but possibly enlightenment is like reaching a

steady state of maximal meaningfulness (or zero separate bits of info, since all is on big correlation).

Ultimately, is MPI **consistent** with self-transcending consciousness? Largely, yes, in the sense that it doesn't conflict; it even provides a scientific echo of some mystical assertions (interconnection, observer-dependent reality). But MPI remains a model of phenomena in duality (it assumes systems and environments and exchange of info). Enlightenment transcends that subject-object schema, so MPI might simply *cease to apply* at absolute nonduality, just as physics equations break down at singularities. An enlightened person, when they return to ordinary functioning, might still be modeled by MPI for any psi that happens in their vicinity, but in their pure awareness state, could say they are in the “unobservable domain” – the endo-ontology that Primas mentioned as experimentally inaccessible. Enlightenment could be accessing that foundational level directly. MPI doesn't describe what that is, but intriguingly acknowledges such a level (ontic states not fully capturable by measurements).

From a practical view: *Academic Research on Enlightenment* documented that these states can be studied in labs (fMRI, surveys, etc.). MPI might encourage including psi tests in such research. If nondual meditators truly quiet the dualistic mind, perhaps they might show psi more reliably in subtle ways. Some past studies did find long-term meditators had higher scoring in Ganzfeld telepathy trials and such, though results vary. It's an open area where the models of consciousness and psi could fruitfully intersect. A nondual framework might even offer an explanatory boost to MPI: psi works because at a deep level mind and matter are not-two (advaita – not two). MPI basically says mind and matter are entangled (nonlocally connected) in a system; the mystic says mind *is* matter ultimately (or both are expressions of a deeper reality). These aren't contradictory – one is phenomenological, one ontological – they can complement each other. In fact, one could argue MPI's refusal to specify the “substrate” of psi and its reliance on an almost metaphoric use of entanglement might be because **consciousness itself underlies these correlations**, a hint at a monistic

reality. In a fully enlightened perspective, you wouldn't even call it psi – it's just the play of one consciousness.

To wrap up: MPI is not a theory of enlightenment, but it can engage with those ideas meaningfully. It suggests why enlightened folks might experience paranormal phenomena yet not flaunt them, and why trying to force enlightenment experiences into transmissible formulas often fails (just as trying to force psi fails). Enlightenment is often said to be “caught, not taught” – an irony similar to psi's elusive nature. But may require a **loss of control or surrender** to manifest. In that sense, MPI's ethos – that you must allow and not grasp – is mirrored in spiritual practice: you can't brute-force awakening; you prepare conditions and let grace or insight happen. Likewise, you can't brute-force psi; you set the stage and let synchronicity come. The *Veil of Ignorance* (to use the phrase from the article) is perhaps our conventional sense of separateness, which once lifted, reveals a reality where things like psi are no longer abnormal at all. MPI provides a scaffold for understanding those anomalies in the unawakened state, and hints that if we were all enlightened, the distinction between “psi event” and “normal event” might disappear entirely, as everything would be an expression of the one mind in flow.

We have covered a lot of theoretical ground. To concretize the insights, our final section will present a **taxonomy of anomalous phenomena** – analyzing each through MPI's principles: what MPI would predict or accept, what it would reinterpret, and what it would cast doubt on. This will serve as a practical summary, distinguishing authentic entanglement phenomena from likely illusions or misinterpretations.

Non-Human Intelligences, Flatland Physics, and the MPI Constraint

Why Would Contact with NHI Feel Dreamlike?

If non-human intelligences (NHI) are real, why do encounters so often resemble dreams, visions, or other highly subjective experiences? The **Model of Pragmatic Information (MPI)** offers one possible answer: it posits that psi-like interactions (and by extension any higher-order “contact”) are **non-causal, meaning-based correlations**.

that can only flourish inside *closed loops of shared meaning*. In other words, genuine contact may require an “**endogenous**” context – a tight, self-contained bubble of meaning (a personal vision, a ritual, a trance, a liminal encounter) – and it **falls apart under an “exogenous” lens** of public, objective scrutiny. MPI’s *non-transmission (NT) axiom* says that psi effects cannot turn into a usable signal; they remain **correlations that vanish when one tries to broadcast or exploit them**

workshoppsitheory.files.wordpress.com. This could explain why any would-be alien encounter or psychic event seems strongest in private, altered states and **collapses under observation** – a kind of “observer effect” for anomalous phenomena. In MPI terms, once you drag the experience out of the closed meaning-system (the vision quest, the ayahuasca session, the haunted bedroom) and into the bright light of a press conference or lab experiment, the organizational closure breaks and the phenomenon **dissolves or evades capture** workshoppsitheory.files.wordpress.com.

Another implication of the NT axiom is that any authentic contact will manifest in **non-reproducible, symbol-laden ways** rather than as a clear physical event. If an alien intelligence or interdimensional being tries to interact, it cannot send a straightforward, testable signal without breaking the rules of the game. Instead, the contact emerges via “**non-signaling channels**”: dream imagery, meaningful synchronicities, telepathic impressions, **sleep-paralysis visions**, psychedelic encounters, experiences, and other forms of high strangeness. These modes are **non-exploitable** – they can convey *meaning* to the experiencer, but they can’t be converted into a reproducible technology or proof. In MPI language, the contact is an **acausal correlation** within the person’s or group’s experience, not a transmissible piece of information. This aligns with the often-noted fact that UFO and encounter experiences feel *personal and subjective*, laden with symbolism and often followed by frustration when one tries to demonstrate them to others. It’s as if the phenomenon **deliberately resists being turned into hard evidence**, which is exactly what MPI predicts (the NT axiom forbids it becoming a public, causal signal).

MPI also suggests a form of **complementarity** at work: certain aspects of these encounters may be mutually exclusive. You can have a vivid, “**real**” **subjective encounter** or you can have **objective measurability**, but not both at the same time. ‘more *objective* you try to make the phenomenon (cameras, instruments, skeptical observers), the more it **withdraws into ambiguity**. Conversely, in the moments it is intensely *subjective and meaningful*, it defies capture by instruments. This is analogous to wave/particle complementarity in quantum physics – the phenomenon presents one face or the other depending on how you look, but you can’t pin down both simultaneously. Under MPI, this isn’t evasion or trickery per se; it’s the **natural behavior of a phenomenon that lives in the borderland between mind and matter**. *must* remain elusive to one frame if it is to be real in the other. The encounter thus often feels like a **lucid dream** – hyper-real to the experiencer yet implausible to outside observers – because it’s *happening in a channel that by design does not cross over into our public, physical consensus reality*.

Finally, MPI’s focus on **meaning** provides a clue as to why NHI encounters wear dreamlike, symbolic guises. If an otherworldly intelligence exists in some higher-dimensional “Outside,” it cannot just barge into our 3D world as itself; it must **project into our reality via the templates of our own minds and culture**. Jacques Vallée’s “control system” hypothesis comes to mind: the idea that UFO and entity encounters mirror cultural expectations and play the role of a **mythic drama** more than a literal invasion. Indeed, UFO lore shows a progression of forms (airships in the 1890s, saucers in the 1950s, black triangles in the 1980s, “tic-tac” objects today) that track with our cultural imagery. The phenomenon seems to “**morph to fit the culture observing it**,” **presenting itself in terms the witness can understand**, much like a 4D being casting a 3D shadow in whatever shape will make sense danieldashnawcouplestherapy.com. In Vallée’s terms, these encounters “**insist on meaning but refuse to resolve into fact**”, delivering a personal message or transformative shock without handing over a piece of hardware as proof danieldashnawcouplestherapy.com. MPI provides a framework for this: **meaning selects the mask**. The shared meanings and unconscious expectations of the witness

(or society) effectively *choose the form* the encounter takes. A medieval peasant in a religious frame might see an angel; a modern pilot sees a technology-defying craft danieldashnawcouplestherapy.com. The underlying contact may be the same “high” phenomenon, but what we get is a **culturally encoded metaphor** – a projection that our psyche can accept, delivered via symbols and narratives that resonate for us. All this keeps the contact *within* a realm of personal significance and **out of the realm of objective interference**, consistent with MPI’s rule that the phenomenon remain an internal correlation, not an external causation.

A Higher-Dimensional “Flatland” Perspective

The classic parable of **Flatland** (a 2D world visited by a 3D being) offers a useful analogy for why NHI encounters might be so strange and hard to pin down. If we imagine humans as 3D creatures embedded in a 3+1 dimensional spacetime, and suppose that NHI operate in a **higher-dimensional or orthogonal realm**, their interactions with us would be inherently limited by what our domain can handle. From the MPI viewpoint, any “**5D being**” trying to interface with **3D humans** would face a kind of information bottleneck or barrier condition. They could not simply step full into our world without losing something (just as a 3D sphere passing through Flatland can only appear as a 2D circle cross-section). Instead, the contact would come through as **partial projections and strange cross-sections** of their full reality. This means high ambiguity: a higher-dimensional event *aliasing* into our lower-dimensional percepti might appear as flickering lights that defy distance judgment, or a being that is “there and not there,” or voices and visions that have a paradoxical quality. **Information is lost in the projection**. The encounter will feel surreal, dreamlike, or beyond normal logic because we’re only seeing a **fragment or symbol** of a larger reality. In effect, a → 3D contact might inherently look like a dream or hallucination from our side, because that’s the only way our limited “Flatland” minds can register it.

Crucially, if there is a physics linking these layers, it likely includes a **non-signaling constraint across domains**. In quantum physics, we learn that even entangled parti

cannot send usable signals faster than light; only correlations (with no control) show up. By analogy, a higher-dimensional being interacting with our world may be bound by a **generalized no-communication theorem**: they can correlate with us (influencing meaningful coincidences, subjective experiences) but **cannot inject a definite, causal influence** without breaking either our reality's consistency or their own. This would forbid the proverbial "landing on the White House lawn" – broadcasting their presence unambiguously in our physical space might simply be **against the rules of the larger game**. Instead, any inter-domain contact must be subtle and **aloof from direct causality**: nudges and hints that **skirt the edges of our reality's causal structure** much like a 3D being lightly perturbing a 2D world without fully crashing into it.

We can think of a **causal-paradox firewall** protecting each domain. If an interaction would create a gross violation of our known physics or a paradox in our timeline (for instance, widely reveal advanced knowledge or technology we're not "meant" to have), the interaction cannot stabilize in plain sight. It's confined to the shadows, the personal and liminal spaces where it can happen *without* rewriting the public rulebook. This is not to say there is some conscious deity enforcing "prime directives," but rather that **incompatible realities naturally meet only in limited ways**. They find workarounds: the **contact expresses itself in dreams, symbols, and tricks** because a full-fidelity exchange is prohibited by the very structure of physics (much as a square and a sphere have no full-fidelity intersection – only a circle, temporarily). In MPI terms, the only viable bridge between such different "organizationally closed" layers is one of **meaningful correlation, not energy exchange**. The higher reality can *tickle* ours at points of resonance – e.g. during altered states or at sacred sites – but as soon as we try to **pin it down in our framework** (measure it, repeat it, weaponize it), decoherence sets in. The phenomenon "**sees you looking**" and **changes state**, so to speak, just as quantum systems do when measured workshoppsitheory.files.wordpress.com.

This perspective helps explain why encounters often have that **blink-and-it's-gone quality** or occur when the witness is in an altered state of consciousness. The phenomenon may actually require a sort of *permission* from our side – a receptive

mental state that creates a small pocket where the usual rules relax. In states of reverie, vision, or extreme emotion, a person's consciousness might serve as the **projection screen for a cross-domain interaction**. But drag that event into broad daylight with multiple observers and cameras, and the "screen" dissolves – our collective reality literally **decoheres the anomaly** by demanding it meet too many criteria. Anecdotally, this is reflected in cases where UFOs vanish when fighter jets approach, or shy away from populated areas, or where high-strangeness events plague certain **liminal hotspots** but never step beyond into consensus reality. It's as if **the phenomenon can occur only in the twilight**, in the cracks of spacetime where it wobbles between the two worlds.

The Trickster Effect: Patterns of Elusiveness

Researchers like Jacques Vallée have often described the UFO/NHI/cryptid phenomenon as having a **tricksterish quality** – a penchant for peek-a-boo games, absurdity, and half-truths that tantalize but never fully resolve. Far from being a mere quirk, this could be a direct signature of the deeper rules we've been discussing. MPI in fact predicts exactly these patterns as a consequence of the NT axiom. Across many accounts of psi and high strangeness, four recurring **signatures of "the trickster"** show up consistently:

- **Decline over time:** An initial surge of strange or psi phenomena tends to **fade with repetition or scrutiny**. Many UFO flap areas or psychic experiments start with striking results that **diminish on subsequent attempts**, often regressing to the mundane. MPI explains that the **novelty and uncertainty** that fueled the initial phenomenon inevitably drop once people try to formalize or expect it, so the effect dries up as the system settles into equilibrium.
- **Displacement to the side:** If you lock down one channel to catch the phenomenon, it **pops up in another**. For example, if investigators set up rigorous cameras, the phenomenon might only influence something odd in the witness's dreams or on an unmonitored sensor. In laboratory terms, when a target outcome is tightly constrained, any anomalous effect may "migrate" to a different,

uncontrolled variable. The **meaning seems to find another outlet** – a kind of evasive maneuver that thwarts direct measurement.

- **Ambiguity and absurdity:** The content of these encounters often seems calibrated to be **just deniable enough**. UFO encounters give fleeting radar blips, blurry photos, or contradictory witness reports – just enough data to intrigue, never enough to conclude definitively. Encounters often feature absurd elements (owl that talk, nonsensical messages, beings performing bizarre “tricks”) as if to undermine any simple literal interpretation. This **ambiguous quality is not a bug but a feature** in MPI terms: it ensures the experience remains in the realm of personal meaning, **unsuitable as courtroom evidence**. The phenomenon insists **being interpreted**, not simply observed.
- **Context dependence:** Strange encounters cluster in **liminal contexts and states** at **meaning-rich times and places**. They happen to lone individuals or small groups on vision quests, during grief or existential crisis, at **sacred sites**, in the deep wilderness, at midnight. These are contexts where observers are psychologically primed, or “organizationally closed,” and thus entanglement correlations can blossom. Bring in a large, disinterested crowd in broad daylight and nothing happens. This **selectivity of context** is exactly what MPI predicts: high meaning, low external interference = greater anomaly; low meaning, high interference = none. As a result, the phenomenon almost *cultivates* a trickster persona – it shows up when it wants, to whom it wants, and disappears if chased.

These traits – **decline, displacement, high ambiguity, context-specificity** – form a pattern long noted in folklore and paranormal research

workshoppsitheory.files.wordpress.com. Rather than dismissing encounters that exhibit these maddening qualities, MPI suggests we should recognize them as the *hallmarks* of a real phenomenon constrained by a non-signaling rule. The trickster is, in a sense, **physics wearing a mask of mischief**. It’s the same “sheep that hide from the shepherd’s spotlight,” in Walter von Lucadou’s poetic phrase for how psi effects move out of reach when hunted workshoppsitheory.files.wordpress.com

workshoppsitheory.files.wordpress.com. The universe isn't necessarily playing pran on us; it's **simply that any cross-domain interaction must behave this way** to exist all without breaking reality. Appreciating this pattern can shift our mindset: instead asking for straightforward proof (which will likely never come in trickster territory) we start looking at **relationships, correlations and meaningful patterns** as the evidence of contact.

Designing Contact Protocols Under MPI Constraints

If one takes MPI seriously, then any effort to **facilitate contact or study these phenomena** should respect its rules. In practice, this means doing almost the opposite of a conventional scientific crackdown. Here are some **guiding principles** for a “**contact protocol**” consistent with MPI's constraints:

- **Small, coherent containers:** Work with **small groups or individual settings** where a tight bond or shared intent can form. A close-knit circle in a ritual or meditative mindset is more likely to create the necessary **organizational closure** than a large random crowd or heavily publicized event. The goal is to cultivate an “**endo-system**” – a self-referential bubble of meaning – in which anomalies can materialize.
- **Non-instrumental stance:** Approach the encounter as an experience to be shared or a relationship to enter, **not as a technology to exploit** or a “test” to pass. In other words, don't turn it into a performance or demand. **No “perform on cue” expectations.** Participants should adopt a mindset of openness and communion rather than trying to force a display. (MPI predicts that the moment you **try to squeeze a useable signal out**, the effect will vanish.)
- **Measure correlation, not signal:** If you use scientific instruments, set them to **look for subtle correlations** rather than a big obvious effect. For instance, you might run multiple random number generators (RNGs) in the background to see if their outputs become non-random in **synchrony** during the encounter window, rather than expecting one big spike on a single gauge. Or you could monitor

participants' physiological measures (heart rate, EEG) for unusual **coordination spikes** among the group. The idea is to catch **patterns of relationship** (e.g. between people's thoughts and an RNG's behavior) rather than a direct message.

- **Pre-register and blind analyses:** To avoid self-deception and “fishing” for anomalies after the fact (which can inflate false claims), use solid research practices: **pre-register** your intended time window or variables, and keep analysis blinded to which data segments were “during the contact attempt” until after analysis. This way any correlations found carry more weight. At the same time, don't provide real-time feedback of results to participants – you don't want to collapse the uncertainty too soon by showing them data as it happens. Maintain a gentle observational stance and **only reveal the patterns later**, preserving the closed system during the attempt.
- **Look for multi-channel coherence:** Given the trickster's tendency to displace effects, design your observation in multiple channels. For example, combine **subjective reports** (dreams, intuitions, odd sensations) with **objective monitors** (RNGs, magnetic sensors, cameras) and **environmental cues** (animal behavior, equipment anomalies). If a genuine correlation is afoot, you might detect a **constellation of small effects** across these channels – say, two people have complementary dream images *and* an RNG shows a deviation *and* a odd brief bl appears on a camera. No single piece would be definitive, but together they form a picture. You're looking for a **weak but coherent signal across many forms**, which is more plausible under MPI than a strong signal in one form.
- **Predict and check against MPI patterns:** Use MPI's own predictions as a guide and test of authenticity. For instance, you might predict that any striking anomaly will **decline on repeat attempts**, or will **shift to another form** if you try to constrain it (displacement). You could even plan a two-phase experiment: first allow a free-form contact attempt, then immediately follow with a highly controlled attempt – and predict that phenomena will appear in the first and vanish in the second. If results bear this out (high weirdness in the open session and low weirdness in the controlled session), you have a strong case for MPI.

nothing in the formal session), it actually strengthens the case that something MPI-like is in play. In short, **embrace the trickster**: expect it, script it into your protocol. If instead you ever find a phenomenon that behaves like a *normal repeatable signal* under tightening conditions, then congratulations – you’ve broken MPI and found something new. But so far, history suggests that won’t happen; instead, the pattern of elusiveness itself repeats.

These principles turn the usual approach on its head. Rather than fighting the ephemeral, subjective nature of the phenomenon, **you work with it**. You create a framework for meaning and then observe gently, from the edges, for any blossoms of correlation. It’s a bit like wildlife photography: you sit quietly in the blind and **let the phenomena come and go**, without chasing it. The result might not convince a hardened skeptic – it won’t yield a spaceship in a hangar – but it could gradually build a **body of evidence in the form of patterns and personal transformations**. At the very least, this approach is testable and consistent: it acknowledges *if the phenomenon is real, it probably can only appear on its own terms, not ours*.

MPI Meets Vallée: Meaning Above Mechanics

Jacques Vallée, noted for his “control system” theory of UFOs, always emphasized that the phenomenon seems to **co-evolve with our consciousness and culture** rather than behaving like a straightforward extraterrestrial visitation. MPI provides a kind of rulebook for exactly *how* such a mutual dance might work. Under Vallée’s view, UFO encounters and other anomalies act as a **cultural feedback mechanism** – they nudge our beliefs and symbol systems, sometimes by reflecting them back to us in bizarre new guises. MPI agrees that **shared meaning is the driver**: it’s the collective narratives, archetypes and expectations that provide the “slot” into which the phenomenon inserts itself. In our modern mythos, space-age imagery dominates, so encounters wear the mask of spacecraft and alien visitors; in earlier ages, religious imagery dominated, so people saw visions of the Virgin Mary or trickster faeries at the edge of the woods. The **content changes, but the underlying form – a meaningful,**

transformative encounter that resists simple explanation – is consistent danieldashnawcouplestherapy.com.

From MPI's lens, we can say **culture supplies the costumes, meaning provides the script**. The phenomenon, whatever it is, doesn't bring a clear message or technology brings a **mirror and a metaphor**. It engages experiencers in a way that's often **person specific**, sometimes even **absurdly tailored to their psyche** (a scientist gets shown a "nuts-and-bolts" craft with seams and rivets, as if to play on his engineering bias; a psychic medium gets a download of spiritual revelations, playing on her mystical framework). This chameleon-like behavior might be the result of a higher intelligence *working through* our own collective unconscious symbols – or it might *be* our collective unconscious in some as-yet-unknown entangled form. In either case, **MPI's no-signature rule demands that the encounter remain in the realm of meaning, not break out into objective fact**. Thus, Vallée's oft-noted frustrating aspect of UFOs – that they leave tantalizing traces but no definitive proof – is exactly what MPI would predict. As soon as UFOs would yield a piece of **concrete, exploitable evidence** (a **piece of metal, a real equation**) that everyone can agree on, the phenomenon would stop being what it is and become a part of our normal world. MPI says *that cannot happen under its constraints*. the phenomenon stays **one step ahead of us**, teasing, teaching, but never settling in our trophy case.

We also see alignment in the idea that **encounters flourish in liminal, sacred, or personal contexts** (what Vallée and others might call "forcing functions" for the control system). MPI's organizational closure is essentially describing a **ritual or liminal space**: a special setting where normal rules are suspended and participants share an intent or mindset. This could be a séance, a vision quest, a haunted house investigation, or even the **psychodrama of a flap area** (where for weeks people are full up sharing UFO stories, effectively creating a collective narrative container). Those are exactly the scenarios where high strangeness tends to erupt. Vallée noted that chasing the phenomenon with too much rational analysis often seemed to make it go away; MPI tells us why – **analysis is an outside view that breaks the closed circle**. Instead

experience and participation (with a dash of the *irrational* or at least the non-rational) keep the door open. In sum, Vallée's "mirrors for the mind" concept dovetails with MPI's mandate that psi phenomena draw from the **meanings and needs of a culture**. The phenomenon *plays back to us* what we expect or need to see, but in a way that challenges us, expanding our worldview just a notch without shattering it. It's a delicate balancing act: provoke and subvert, but do not overthrow. **Mystery is maintained** as a kind of developmental pressure. MPI quantifies one reason for the maintenance: **if the mystery were resolved into fact, the special conditions for the phenomenon would evaporate.**

In this light, one can be a *realist* about NHI or UFO phenomena (in the sense that something is truly happening beyond pure hallucination) while also understanding why it behaves so elusively. The **trickster aspect is not an obstacle to be eliminated but a clue to the very nature of the phenomenon.** It suggests that we are dealing with something that operates **through consciousness and information** at least as much as through matter and energy. Vallée once suggested the phenomenon might be a "control system" – not controlling us in a sci-fi sense, but regulating the interface of human consciousness with a larger reality. MPI gives a concrete principle for that regulation: the **no-transmission rule** that prevents a free flow of information between the two sides, ensuring that each experience leaves us with **questions and personal insights rather than engineering specs.** In a way, it *protects* both our reality and whatever lies beyond it, by **keeping the traffic one of symbols and synchronicities** instead of brute facts. We are, perhaps, being slowly **acclimated or taught** – or simply engaging with the *Unknown* in the only manner possible, via a kind of cosmic safe mode that emphasizes inner change over outer proof.

Jung, the Imaginal, and the Complementarity of Mind and Matter

Carl Jung's notion of the **psychoid** archetype anticipated MPI by half a century. Archetypes, he wrote, are "psycho-physical" realities that transcend the mental/physical divide. They erupt as dreams, synchronicities, and apparitions—

precisely the forms that MPI treats as entanglement correlations within organizational closure. Jung's "collective unconscious" can be seen as a vast *meaning field* in which these correlations arise, modulated by cultural symbols.

When NHI encounters mirror archetypal imagery—serpents, lights, tricksters, cosmic parents—this may reflect the system's effort to express a higher-dimensional pattern through the symbolic grammar of the psyche. The encounter thus takes place in what Henry Corbin called the **imaginal realm**, the intermediary domain where mind and world co-create experience. MPI describes the dynamics; Jung and Corbin describe the phenomenology.

Fourth Wall Phantoms

Fourth Wall Phantoms essentially argues a similar dynamic: that **fictional narratives and folklore can literally manifest in reality** as paranormal encounters. The book documents many cases where UFO sightings, cryptid encounters, and ghostly phenomena **mirror elements from prior fiction and legend** joshuacutchin.com. As one commentator put it, "our fictions are alive, real, and interact with us constantly" joshuacutchin.com. MPI offers a possible mechanism for this crossover between imagination and the real world. Since meaningful information can generate genuine psi effects, a powerful story or belief system can act as the driver for an anomalous event. A culturally shared legend or personal belief serves as pragmatic information that seeds an experience of the very phenomenon described in the narrative. In this view, a well-established myth or fictional archetype can **break through the "fourth wall"** into tangible reality once it carries enough psychological and cultural weight. Reality effectively yields to the narrative under these conditions, much as MPI predicts entangled correlations will form around meaning.

MPI also clarifies why these fiction-driven anomalies are so fleeting and difficult to pin down scientifically. Because the phenomena rely on narrative context, they tend to occur spontaneously in emotionally charged, meaningful moments—conditions that cannot be easily reproduced in a lab. As Lucadou observes, the strongest psi events

happen in “live” situations rich in personal history, whereas controlled experiments produce only tiny effects. In everyday life, an encounter with a fictional entity is embedded in personal and cultural context, giving the incident “enough possibilities to link with” meaning. But under rigorous observation—where the story is stripped away—such events usually evaporate. This echoes Cutchin’s notion that **the laws of the universe behave more like guidelines that crumble under narrative influence**. MPI terms, applying a compelling narrative effectively loosens normal physical constraints, allowing one-off “impossible” happenings; yet those constraints snap back once the narrative influence fades, making these wonders hard to repeat on demand.

Could Physics Itself Enforce a Contact Limit?

All of this leads to a profound question: *why* would the universe be set up in such a way that two realms (ours and the NHI/psi domain) can only touch via these oblique, non-causal means? Is there an underlying physical principle that **forbids direct inter-world communication**? Interestingly, many threads in mainstream physics hint at exactly this kind of limitation – a sort of **cosmic censorship of cross-domain signals** that might be very general. It could be that what we’re calling “MPI’s rule” or a “no-communication across layers” principle is a deep feature of reality that shows up in different guises in quantum mechanics, relativity, and information theory.

One clue comes from **quantum non-signaling**. In quantum mechanics, entangled particles can have strong correlations, but those correlations can’t be used to send a message. This is formalized in the **no-communication theorem**: no matter how much two particles seem to “influence” each other instantaneously, you can’t control that influence to transmit information. MPI essentially **takes this idea to the macro level**. It says psi phenomena are like entanglement-like correlations in the macroscopic world – *meaningful coincidences* rather than signals – and as such they obey a similar non-signaling rule. Now, if NHI exist in some higher plane or outside our familiar spacetime, one could speculate that **any interaction between their domain and our**

falls under a generalized non-signaling mandate. In other words, the only kind of influence allowed is the “lined up coincidences” type, not the straightforward send-bit type. This ensures that **causality in each domain remains self-consistent** (no paradoxical information leaks) while still allowing **correlations that hint at a connection.** It’s a bit like two separate quantum systems that can become entangled: they share information in an *implicit* way, but neither can be said to have sent a message to the other. For an NHI encounter, this would mean they *can* influence our thoughts or perceptions in synchronistic ways (and we theirs, perhaps), but neither side can just hand the other a piece of hardware or a set of equations that didn’t originate within that side’s universe.

Another relevant principle is from **relativity**: the lack of a universal present and the cosmic speed limit on signals. Relativity tells us that there is no single “now” that all observers share – time is woven with space, and cause/effect is local, constrained by light speed. If an NHI exists in a realm with a different spacetime structure (or outside spacetime as we know it), establishing a common reference frame for communication could be fundamentally impossible. Any attempt to send a concrete signal might violate the causal order in one realm or the other. Thus, **only acausal correlations – which don’t carry a real signal and hence don’t violate causality – can get through.** It’s as if the universe says: “You can *align* outcomes between realms, but you can’t send a **flash of light** or a phone call.” This is similar to how in some interpretations of quantum theory, information from the future or outside time could influence outcomes (as in retrocausal models) but **only in a way that looks random to anyone except an informed observer.** In simpler terms, if two domains don’t share the same clock and yardstick, the **only safe bridge is one that doesn’t carry force or energy – only correlation.** This might be why contact often happens in altered states or dreams where our normal sense of time and space is loosened; those are conditions under which an “outsider” might briefly interact without causing a physics aneurysm.

The **Flatland analogy** we discussed can be taken as a literal physics hypothesis too. Higher-dimensional reality interacting with a lower-dimensional one will produce

phenomena that are **low-dimensional shadows** of higher phenomena. This typically means they are **underspecified and strange**, like a 3D object appearing as a changing 2D cross-section. If a being from 5D tries to “push” into 3D, you might just get a wobbly shimmering shape or a momentary anomaly – something that doesn’t fully add up, because the bulk of its reality is outside our perception. Additionally, any **information-rich interaction** from 5D would appear to us scrambled or paradoxical (much as a 3D object’s features get jumbled in 2D). This could account for why NHI encounters often have that **dream logic** – events happen out of order, beings communicate telepathic (because our ears can’t pick up 5D vibrations, so to speak), and physical evidence is inconsistent. It’s all our 3D brain can manage when faced with a slice of a higher realm. Furthermore, such partial projection might inherently **degrade if you try to hold it steady**. It’s a bit like trying to keep a higher-dimensional hologram stable on a lower-dimensional screen – it will flicker and break apart if scrutinized too long. So again, you get brief, personal flashes of contact, but no enduring artifact.

Beyond these intuitive parallels, it’s fascinating that **several advanced physics frameworks echo the idea of “correlation without full communication”** when it comes to information across boundaries:

- **Quantum decoherence (Quantum Darwinism):** In quantum theory, a definite, stable fact emerges only when information is **redundantly recorded in an environment** (multiple observers or copies) quthermo.umbc.edu. If an event isn’t widely measured, it remains a non-committal haze. By analogy, an NHI encounter might only ever be **clear to the one who experiences it**, and the moment you try to get redundant measurements (multiple cameras, observers), the “quantum-ish” aspect fades and no classical fact (UFO landing) ever crystallizes. The phenomenon might require *remaining partially unobserved to persist*, much like a fragile quantum state.
- **Retrocausal and two-time physics:** Some interpretations of quantum mechanics (and theories like the transactional interpretation or the two-state vector formalism) allow influences that run **backwards from the future**, or generally,

boundary conditions that affect outcomes without a forward-in-time signal. These models create **correlations across time that are real but not usable to send messages** (you can't paradoxically send tomorrow's lottery numbers to today, but tomorrow's state can bias today's quantum outcomes in undetectable ways). This is analogous to our situation: if an NHI exists in what amounts to "our future" or outside time, maybe they can only **nudge outcomes probabilistically**, never in a way that lets us send a packet of data back and forth. We get *signs* and portents, perhaps, but never an explicit conversation that would violate time's flow.

- **Holographic or emergent space-time theories:** In some cutting-edge physics, spacetime is seen as an **emergent phenomenon from more fundamental information networks (entanglement patterns)**. Different "bulk" realities might emerge from different entanglement structures. Communication between such realities might be forbidden unless there is some overlap in the underlying information network. If an NHI is associated with a different branch of the information network (another "universe" or emergent layer), then direct interaction is like trying to share data between totally separate hard drives – not possible *except* if there is a pre-existing entanglement or shared simulation layer. Any contact then might occur only via that deep entanglement – showing up to us as bizarre quantum-like correlations, where something flickers in and out. It would explain why **the phenomenon is elusive and can't be summoned at will**: not part of the normal circuit of our reality, only a glancing connection through the underlying matrix that usually keeps realms separate.

Each of these examples, while speculative, shows that **modern physics doesn't outright laugh at the idea that information transfer might be fundamentally limited across certain boundaries**. In fact, it seems to be a theme: Nature abhors information flowing freely between domains that don't normally connect. There's always a catch – damping, a noise curtain, or a one-way screen. MPI's rule for psi – "you can't beam like a signal, you can only coax it as a correlation" – might be just one instance of a very deep cosmic rule. Perhaps **causal autonomy is a conserved quantity**, just like

energy or momentum. Each coherent world or domain (a spacetime, a quantum system, a conscious mind) **keeps its own counsel**; you can line up with another domain (become entangled), but you cannot rob one to pay another in terms of information.

Why might such a rule exist at all? We can only speculate, but a few principles come to mind:

- **Causal self-consistency:** If unrestricted signals could flow between fundamentally different realms or timelines, you'd invite paradoxes (the grandfather paradox, violations of causality, etc.). A non-signaling rule across domains **prevents paradox** by ensuring no domain can be used to contradict itself via another.
- **Entropy and conservation:** Our universe has its own bookkeeping of energy and entropy. A direct injection of information (especially usable, low-entropy info) from an external source would be like a violation of the second law or other conservation laws. By only allowing subtle correlations that are woven into the fabric, the **balance of each universe is preserved**. No free lunch of negentropy from outside.
- **Ontological isolation (closure):** Each level of reality might be an “island” that **only develop according to its internal rules**. This could be a design principle (if one believes in such) or simply a natural fact of a multiverse – domains don't collapse into each other because they're built to be self-contained. Interactions can happen, but only in ways that don't collapse the autonomy of either side.
- **Cognitive bandwidth mismatch:** On a less mechanistic note, maybe the limitation exists because minds like ours literally **cannot process a direct encounter** with vastly different reality. Our brains and perceptual systems evolved for a certain slice of existence. Like an ape trying to understand the internet, there's only so much we could receive even if an advanced being tried to communicate. Thus, contact has to be **dumbed down to symbols and archetypes** (which our psyche can handle) and often delivered through dreams and altered states (where our **filter routines are relaxed** enough to let something novel in). If they tried to “land on

the lawn” and that physics, we might not even perceive it properly, or it could fool our circuits. The safest route is through the *native language of our unconscious* – myth and experience – which by its nature feels nebulous and personal.

All these reasons circle a common idea: **Reality protects itself**. Just as physics has cosmic speed limits and uncertainty principles, there may be a kind of **communication firewall between layers of reality**. You can have **entanglement** (relationships that only show up when you consider the two sides jointly), but you can’t have brute force messaging that would collapse the distinction between here and *there*. If NHI and other “weird” phenomena are real, they might be **bound by this firewall**. In fact, their elusiveness could be evidence that such a principle is in effect – it’s the reason they *have* to be elusive.

This perspective even gives us a hopeful hint about our own physics. It suggests that our current separation of the world into “causal physical” and “acausal psychic” might one day be bridged by a **new principle of complementarity or correspondence**. We have long-standing dualities (wave/particle, energy/time, etc.) in science; maybe **causal vs. acausal** (or **material vs. meaningful**) is another duality we need to formally recognize. MPI essentially proposes such a complementarity: you can have phenomena that are either **causal signals** or **acausal correlations** depending on how you set up observation, but not both. This resonates with the fact that **quantum physics, relativity, and information theory each hint at limits** that, taken together, sound like “you can’t share all the information between systems freely.” Perhaps a future theory will explicitly include a “**Generalized No-Communication Theorem**” that spans physical and psychological domains – a rule that any emergent reality must obey to prevent logical contradictions. This rule might unify threads from quantum non-locality, relativistic causality, and even thermodynamics into one overarching conservation law of informational independence.

In poetic terms, **the universe might impose a kind of sacred boundary around every closed world** – be it a quantum system, a mind, or an entire cosmos. You can touch

across the boundary (entangle, correlate), but you cannot **breach it with force**. The **trickster theater** of UFOs, cryptids, and psi phenomena would then be the natural, law-abiding way that two domains sniff at each other without breaking the glass. It courtship dance of realities, full of flirtation and shadow-play, never consummated full daylight.

A Final Synthesis: If higher intelligences or phenomena are indeed interacting with us, their **dreamlike, trickster behavior** may not be an accident or deception at all – could be the *signature of a deeper conservation law at work*. MPI suggests that the only way two different levels of reality can interact is **through meaning, not mechanics**. The universe, in this view, **protects the causal integrity of each layer** (ours and “theirs”) by permitting only **acausal, elusive, interiorized encounters**. The result is exactly what we see: extraordinary, life-changing experiences that nevertheless **evaporate under public scrutiny**. Rather than landing on the White House lawn, the otherworldly stays at the edge of the campfire light – close enough to spark wonder but never so present as to become mundane. This might frustrate our scientific urge for proof, but it could be the only way two ontologically different worlds can **share a moment of contact** without collapsing into one. In the end, the **dreamlike quality** of these encounters may itself be **the best evidence that they are *real*** on their own terms – obeying a higher-order physics of consciousness and information. The trickster’s grin, the slippery nature of the phenomenon, could well be telling us: *“I’m here, but I won’t meet me, you must step out of your hard reality for a while... and I can’t step fully into your world.”* Far from dismissing such experiences, MPI invites us to take them seriously *and* take their very elusiveness as a clue. The **impossible is allowed – but only in the imagined space** where it won’t break the world. And perhaps that is the profound lesson: reality is broader than the solid things we can all agree on, and at its fringes lie meanings that tease us toward growth, one whispered paradox at a time.

Psi and Anomalies Under the MPI Lens: A Taxonomy of the Unexplained

The world of the paranormal and anomalous is vast, ranging from relatively subtle experiences (like intuitions and dreams that later prove true) to grandiose claims (like levitating gurus or materializing UFOs). Using MPI as our guide, we can attempt to classify these phenomena and assess them:

- **Dream Precognition:** Many people report dreaming about events or symbols that later show up in real life in uncanny ways. MPI would view **dream precog** as a prime example of a psi phenomenon that is *real but inherently ambiguous*. In a dream state, the mind is free-ranging and not actively trying to “send or receive signals. This puts the experiencer firmly in the **unintentional, endo** mindset conducive to psi. If a dream later matches an event (say dreaming of a tsunami the night before a newsworthy tsunami occurs), MPI would interpret it as an **entanglement correlation** between the person’s psyche and the forthcoming environmental event – established through the shared meaning or emotional resonance (e.g. the dreamer had family on the coast, and unconsciously that connected them to the event). Crucially, MPI’s NT axiom predicts that dream precognitions will almost always be recognized **only after the fact** – not in a way that could allow warning or prevention. Indeed, most dream precog anecdotes are like “I dreamed of a plane crash and the next day one happened,” rather than “I knew which plane would crash and saved someone.” The symbolic nature of dreams also fits MPI: the information is not literal (that would make it a transmittable signal), but often metaphorical or approximate, maintaining that haze that prevents exploitation. *MPI accepts dream precognition* as plausible and even expected under its framework (because dreams are a classic example of a closed subjective system where novel pragmatic info can seep in). However, it would **reinterpret** claims of ultra-clear prophetic dreams (like someone dreaming the exact winning lottery numbers) with skepticism – either chalking them up to chance coincidence (someone somewhere will dream numbers that hit, out of millions of dreams) or suspecting narrative embellishment. Dreams that come in broad outlines, especially ones tied to personal meaning (like sensing a loved

one's death in a dream before you get the phone call) are more MPI-consistent than highly specific or self-serving prophecies.

- **Telepathy and Clairvoyance (ESP):** Classic ESP (extra-sensory perception) includes telepathy (mind-to-mind) and clairvoyance (perceiving distant scenes). Under MPI, both are seen not as literal “transmissions” of thoughts or images, as **correlations between mental and external states**. For example, in a telepathy test with Zener cards, if the “sender” is focusing on a symbol and the “receiver” across the room guesses it, MPI would say the sender-receiver pair (plus cards) formed an entangled system such that the receiver's responses correlate nonlocally with the card drawn. Importantly, MPI predicts that these correlations will be statistical and prone to decline over time or repeated testing, as discussed. It also predicts that if the experimenters tried to use telepathy as a secure communication channel (say, transmit a code every day at 9am reliably), the success would evaporate (NT axiom). Telepathy in spontaneous cases – like a mother suddenly knowing her child is in danger – is more likely to be genuine than MPI standards, since it's unplanned, emotionally charged (meaningful), and not repeatable on demand. MPI would **accept ESP phenomena** that occur under such organic conditions or mild lab conditions (Ganzfeld experiments, etc., which indeed have produced small but significant above-chance results in meta-analyses). But it would **reject simplistic interpretations**: e.g. it's not that a “thought” as a packet traveled across space, but that the two minds were briefly one system with a shared informational state. In everyday terms, MPI-compatible telepathy might feel like *“I just suddenly thought of you and felt you needed help”*, or like hearing a voice in your head giving an address (which would be more like a radio signal scenario – suspicious under NT). Clairvoyance (seeing distant scenes) similarly would come as impressionistic images or intuitions, often needing interpretation, rather than a crystal-clear “remote camera feed.” This matches the actual phenomenology reported by remote viewers: they often get shapes, emotions, or rough sketches right, but rarely exact details like proper nouns or numbers (those that claim consistent detail likely are over-claiming).

- **Psychokinesis (PK) – Micro and Macro:** PK is the alleged ability of mind to influence physical matter or events. **Micro-PK** refers to small effects, often only detectable statistically, such as influencing random number generators (RNGs) affecting the fall of dice a tiny amount. **Macro-PK** means observable large effects – objects moving with no apparent cause, spoon bending, levitation, etc. MPI's stance is that **PK is real** but almost exclusively manifests as **micro-PK or spontaneous macro-PK in special contexts**. Laboratory RNG experiments have accumulated evidence of slight deviations when people intend to influence them. MPI explains micro-PK as the output and the operator becoming entangled – not a force push, but the outcome being biased to align with the operator's intention in a nonlocal correlation manner. Since the effect is tiny and requires many trials, it stays within NT bounds (no one can take a single RNG and reliably flip bits by mind one by one – they can only shift probabilities a bit, detectable over many runs). This is acceptable because it can't send a message in one go (the noise swamps it short-term). **Macro-PK** like poltergeist phenomena (objects flying, appliances turning on) is acknowledged in MPI literature as RSPK (Recurrent Spontaneous PK). These occur typically in **poltergeist cases around a focal person, often an adolescent under stress**. MPI would accept these as genuine entanglement bursts in a highly emotional, closed family system. The phenomena often carry symbolic meaning (e.g. plates breaking when family tension peaks), aligning with pragmatic information theory that it's the meaning that matters. However, critically, these events resist on-demand repetition. The "focus person" cannot just snap their fingers and do it at will – it happens subconsciously and usually stops if a researcher tries to isolate it under test conditions. MPI predicts the poltergeist activity will die out once the underlying psychological issue is resolved or once it's too closely watched (often indeed poltergeists cease when scientists come, resuming when they leave – a classic displacement). So *MPI accepts macro-PK only in such uncontrolled settings*, and would **reject most claims of voluntary macro-PK** (like stage psychokinesis or people who say they can move objects anytime). Those, MPI suspects, are either delusions or tricks. For instance

spoon bending: many have claimed to do it paranormally (notably Uri Geller, an attendee at “spoon bending parties”). MPI would say if a spoon truly bends anomalously, it likely occurs in a group excitement context where everyone’s belief and perception are engaged (an organizationally closed mini-community) and perhaps many utensils bend a little without notice and one is found bent – a kind of collective PK or even self-bending due to material anomalies induced subtly. But because spoon bending has also been replicated by magicians via misdirection and metal fatigue, MPI would urge caution. It would classify **public spoon bending demos** as likely *pseudo-PK*: maybe a mix of real micro entanglement (the performer’s high confidence and audience expectation entangle to produce one or two inexplicable bends) and actual sleight-of-hand for consistency. The more flawlessly someone bends spoons under bright lights, the more MPI suspects sleight-of-hand, because a reliable, visible macro effect is exactly what NT forbids unless it’s a one-time spontaneous event.

- **Healing and Psi in Medicine:** There are claims of **psychic healing**, prayer effects, homeopathy working via information, etc. MPI, interestingly, has been applied to model homeopathy and healing as *meaning-mediated effects*. MPI wouldn’t accept that “mind is generating energy to regrow tissue,” but it would consider that patient and healer form a system in which health outcomes can correlate with intentions/beliefs beyond what conventional causality would predict. This is akin to placebo effects supercharged – which we know are real. MPI could frame certain alternative therapies as **non-classical pseudo-machines**: they aren’t doing anything physical beyond placebo range, but the ritual and belief create an entangled system yielding an outcome (symptom relief) as long as no one breaks the spell by exposing it as inert. The model actually predicts such effects will fail in RCTs if those trials remove the meaningful context (double-blinding, etc.), because that kills the entanglement. Indeed many healing claims diminish under controlled trials, which skeptics use as debunking, but MPI would say “of course, because you took away the key component – the subjective meaning and belief. So MPI would *reinterpret healing miracles* – accepting that health can be psi-

influenced, but not in a robust, transmittable way. It expects mixed results and need for “belief maintenance” for it to work (hence faith healers succeed in revivals where everyone’s primed, but not in hospitals under scrutiny).

- **UAP (Unidentified Aerial Phenomena, aka UFOs):** This category straddles the psi world and the physical world. Are UFOs craft with aliens (nuts-and-bolts), purely hallucinations, or something interdimensional/psychic? MPI itself doesn’t speak to extraterrestrials, which would be a normal physical phenomenon if real. However, UFO encounters often have high strangeness: e.g. sightings that seem to respond to observer mindsets, apparitions that blink in and out, missing time experiences akin to altered states. Some researchers (like Jacques Vallée) have hypothesized a *psychic component* to UFO encounters, seeing them as an “externalized” form of a control system interacting with consciousness. If one takes that view, MPI could weigh in by treating a **UFO sighting event** as an entangled system between witnesses and an anomalous stimulus. Perhaps certain UFO events are **manifestations of collective entanglement correlations** – meaning multiple witnesses share a meaningful vision triggered by... something (maybe geomagnetic or military flares in some cases, but their minds pattern it into a classic saucer via shared unconscious imagery). MPI would allow that as long as the phenomenon doesn’t yield hard evidence that breaks NT (and indeed UFO evidence is notoriously elusive – clear photos or physical debris are scarce and dubious, which parallels psi’s elusiveness). MPI would **reinterpret UAP** not simply as aliens flying around, but possibly as a modern *cultural form of psi manifestation*. Just as poltergeists occurred in certain eras, perhaps in the atomic age the psyche dresses anomalies as spacecraft. However, if there are true physical craft zipping in the skies with propulsion, that’s outside MPI’s scope (that would be straightforward tech or undisclosed aircraft). MPI’s principles would predict: if UFOs are associated with psi, you’d see personal meaningful experiences (some contactees indeed report telepathy with UFOs or symbolic messages) and a lack of consistently useful interaction (no landing on White House lawn). That matches the erratic, almost tricksterish behavior described in UAP accounts. So MPI m

accept the *weirdest* aspects of UFO lore (e.g. close encounters where reality seems dreamlike and synchronized with consciousness) as hints of entanglement at work, while rejecting simplistic ideas like “anyone can summon a UFO with a flashlight code” – attempts to regularize them often fail or turn out fraudulent.

- **Bigfoot and Cryptids:** Creatures like Bigfoot, Yeti, lake monsters, etc., occupy an anomalous space. If they are just undiscovered animals, that’s cryptozoology, not psi. But the fact that these creatures remain elusive with no hard corpse or DNA despite many sightings, puts them in “folklore made manifest” territory. Some theories even connect Bigfoot sightings with **high strangeness** (lights in the woods, psychic sensations), suggesting it might not be a normal ape but something parapsychological. MPI would likely lean towards skepticism of a breeding population of large primates in North America with zero roadkill or clear photos – that strains normal credulity. If people are truly seeing something MPI might categorize **Bigfoot sightings** as a kind of *entanglement-assisted misperception*: perhaps witnesses in an entangled state with nature (hunters, hikers who deeply invest in the idea of a wild man) actually co-create a brief visual or auditory experience that has meaning (the archetype of the wild man) but no permanent physical evidence (because it wasn’t a physical creature in the usual sense). In effect, MPI could say Bigfoot is a “**pseudo-animal**” – it appears real to the observer (just as a pseudo-signal seems real internally), but there is no biological entity there for an outsider to catch. This would explain why footprint, hair samples, etc. tend to be inconclusive or hoaxes. The phenomenon, if psi-based, would *require belief and context* (once again an organizational closure: often Bigfoot is seen by people who either believe or in locations with a lore). As soon as you bring a skeptical scientific expedition, maybe nothing happens (the closure broken). MPI thus would be open to Bigfoot as a *modern myth that occasionally realizes itself through entanglement correlations*, but it would reject the notion of a stable, material Bigfoot that one could hunt like any animal. Similarly for ghosts/apparitions of the classic kind: MPI sees them as meaningful perception or poltergeist-type effects within a system (family, location), not as literal undead.

spirits roaming at will. It doesn't strictly deny consciousness surviving death (that's beyond its scope), but any ghostly effect must still obey NT – e.g. a ghost might knock once for yes, twice for no in a spooky but ultimately ambiguous way. If a medium starts delivering clear, verifiable info like a fax machine, MPI grows suspicious that normal info channels or fraud are in play.

- **Stage-Magic Style “Miracles”:** MPI is inherently critical of clean, theatrical paranormal demonstrations. This includes things like repeating miracles on schedule (statue bleeding every 3rd Friday, or a guru levitating every time at 5 p.m.). If these truly occur, either they are not psi but some unknown physics (unlikely in many cases), or they are fakes. MPI strongly predicts that any scenario which looks like someone **breaking physics at will in public** is not genuine psi because it violates the condition that psi can't be reliably exploited. Therefore, MPI would put **91** (for example, a person who bends a metal bar with thought alone on cue on a TV show) in the “most likely fraudulent” bin. It would highlight that **ambiguity** and **subtlety** are hallmarks of real psi. So ironically, the more blatant a claim, the less credible under MPI. Truly MPI-consistent cases often have *just enough doubt* that skeptics can say “eh, coincidence” – that's by nature, because if it were beyond doubt, it'd also likely be beyond NT's allowance. For instance, a healer might have 5 patients in remission but 5 not – some will attribute success to prayer, others to medicine. That ambiguity keeps it from being a clear psi signal, which perversely might be exactly why it could be real. This is a sort of *sanity check*: an honest psi researcher might say, “If tomorrow someone shows me a 100% accurate mind-reader machine, I'd actually doubt it's psi – maybe an AI picking up micro-expressions – because real psi doesn't behave so obediently.” MPI encourages that attitude. Not that we can't be open to strong evidence, but we calibrate expectations to psi's known character: **elusive, capricious, context-dependent**.
- **Remote Viewing Commercial Groups:** Under the Model of Pragmatic Information (MPI), apparent successes in remote viewing—even strikingly accurate ones—are not cases of signal transmission. They are **acausal correlations**.

that arise within an **organizationally closed meaning system** comprising the viewer, the tasker, the target, and the social/ritual context. The “right” details surface because of **non-local correlation shaped by shared meaning**, not because information literally travels across space or time. MPI further predicts that accuracy **declines when the system is overly instrumentalized**—for example, when viewers are pushed toward outcome metrics, public proofs, or repeated use as a dependable tool. Commercialization (subscriptions, monetized training, pay-walled tasking) tends to **shift intention from participation to control**. In MPI terms, that invites violation of the Non-Transmission (NT) principle by attempting to **use psi as a signal**. The expected result is **instability**: a mix of shining “hits” and conspicuous “misses,” with accuracy that proves **difficult to sustain** once the practice is packaged as a reliable product. From the MPI viewpoint, the hits can be genuine correlations; the misses are the system **reasserting the NT constraint**. Operational remote viewing frameworks (e.g., groups that forecast specific events) implicitly model psi as **causal perception** that should become **reliably reproducible** with training. MPI models psi as **non-causal, meaning-dependent correlation** that **appears in rich, ambiguous, emotionally engaged contexts and collapses under exploitation or excessive measurement**. Rather than contradicting MPI, the best performances in such groups often **illustrate MPI conditions**: alignment, ritualized protocols, shared belief, and a semi-sacred container. When these are replaced by commodification or mechanization, effects typically flatten. To test these predictions, embed **blind remote-viewing sessions** inside a Wyrdoscope (dual-RNG) protocol and treat the sessions as **meaning events**, not predictive contests. Pre-register windows during which viewers seek or describe targets under **high shared intent** versus windows framed **commercially or instrumentally**. If MPI holds, RNG correlations should **peak in the former and attenuate in the latter**—even when subjective scoring of descriptions looks similar—showing that **profit-driven or control-oriented framings degrade the systemic closure psi needs**. Groups like Future Forecasting Group or Farsight are **not counterexamples** to MPI. They are **living**

demonstrations of its limits: psi can look like reliable information transfer, but reliability **diminishes** once treated as a **signal to sell or control**. Their partial successes **reinforce** MPI's central claim that psi is **entanglement of meaning**, not transmission of data.

To summarize this taxonomy in MPI's terms:

- **Likely Genuine (within limits):** Dream precognition, spontaneous telepathy (especially in crises or emotionally charged bonds), micro-PK (RNG effects), meaningful synchronicities, some haunting/poltergeist occurrences, intuitive knowing or remote viewing that is symbolic/partial. These all involve entanglement correlations that are *small-scale, non-repeatable on demand, and deeply tied to personal meaning*. MPI predicts them, accepts them, and explains why they're hard to formalize.
- **Possibly Genuine but Misunderstood:** Some healing phenomena, mediumistic information that's hit-or-miss, UFO encounters with psychic aspects, cryptid sightings that behave more like apparitions. MPI might reframe these as psi-related effects filtered through cultural narratives. They're not what they appear superficially (not medical panaceas, not literal aliens or animals), but something stranger yet following psi rules. These often have believers and skeptics talking past each other; MPI offers a middle path saying "there is an anomaly, but it's an entanglement of mind and matter, not a straightforward new creature or technology."
- **Likely Not Genuine (as presented):** Highly public, repeatable "wonders": e.g. lottery predictions at better than chance consistently, any product that promises guaranteed psychic results, performers who under controlled conditions do miracles on cue repeatedly. MPI suggests these either fail when truly controlled or have been associated with trickery. Also, phenomena that have zero meaningful pattern and only appear as one-off stories with no context (e.g. random urban legends) might just be hoaxes or mistakes; real psi tends to occur in *systems of*

meaning. If something has no meaningful connection and just defies physics for no reason in a one-off, MPI wouldn't have a framework for it (and it's probably just fake or error).

In all cases, MPI emphasizes **entanglement-like nonlocal correlations, not forceful causation**. So any phenomenon that implies a force (like “telekinetic energy” or “sending out vibes that push things”) is probably a naive interpretation. Instead, MPI would look for the correlation: the spoon bent, but maybe at the exact moment the person had a strong mental release; or the apparition was seen, but only by the person who was unconsciously role-playing a need to see it. It's about linking events via significance.

The taxonomy under MPI also brings out a limitation: **ambiguity is not a bug but a feature** of psi. Cases more consistent with MPI will always have that shadow of uncertainty – that's the price of obeying NT. We thus judge cases not by how clear-cut they are (counter-intuitive for standard science) but by a combination of statistical likelihood and contextual richness. A case with a bit of the unknown that also fits into a meaningful story might actually be more evidential of psi than a flashy claim that stands alone.

Empirical Support for the Model of Pragmatic Information (MPI)

Predicted Signatures of MPI

MPI does not forecast dramatic “paranormal” feats on demand. Instead, it predicts subtle **statistical patterns** that emerge when **meaning** is high but experimental control is low. Key empirical signatures expected by MPI include:

- **Non-causal psi correlations:** Psychological and physical variables may show weak correlations without any normal causal link. These appear as an excess of significant correlations across large datasets, beyond what chance predicts [psi-](#)

psi-encyclopedia.spr.ac.uk. Importantly, no single variable carries a discernible signal; the structure is only evident in the holistic data matrix.

- **Decline effects:** Initially strong psi results tend to **diminish with repetition** or rigorous replication. This pattern has been noted since J.B. Rhine's era (e.g. a striking fall-off in dice-throwing success over time) psi-encyclopedia.spr.ac.uk. MPI explains this as “**pragmatic information**” being used up – once participants get feedback or the novelty wears off, the effect dissipates.
- **Displacement of effects:** If a target outcome is tightly constrained, any psi influence may “**migrate**” to other, **uncontrolled variables**. In other words, the system still finds an outlet for meaning to manifest, just not necessarily where experimenters initially look.
- **No direct, usable signal:** Any psi effects only become apparent **in retrospect**, as statistical anomalies – never as a real-time, information-carrying signal. This elusiveness is by design: MPI posits psi is an acausal correlation akin to quantum entanglement, which **cannot transmit information** without breaking fundamental laws psi-encyclopedia.spr.ac.uk psi-encyclopedia.spr.ac.uk. The upshot is that psi will reliably **evade protocols** that seek to capture a repeatable signal.
- **Context and meaning dependence:** Psi-based correlations should strengthen in situations with shared meaning, emotion or ritual. In **high-coherence contexts** for example, group meditations, intense rituals, emotionally charged gatherings small anomalies are expected to **flourish**. These are essentially “entanglement-friendly” settings where a temporary **organizational closure** (a self-contained system of mind and matter) can form. Many experiments indeed report that when participants are emotionally or mentally synchronized, random devices begin to deviate slightly from chance gowyrd.org.

MPI's core claim is that such effects are signatures of an entanglement-like connection within a **closed psychophysical system**. No energy or force is transmitted; instead, meaningful correlations appear acausally – and only as long as the system remains **structurally intact** (once disrupted or observed from outside, the effect

collapses). We next review the empirical findings over the past few decades that exhibit these characteristics.

Lucadou's Correlation Matrix Experiments

The earliest experimental support for MPI came from Walter von Lucadou's work in the 1980s on the **Correlation Matrix Method (CMM)**. In these studies, human participants tried to "influence" an unpredictable physical system (such as a random number generator) much like a standard micro-PK experiment – **but** the primary measure of success was not a shift in the RNG output itself. Instead, dozens of **psychological** variables (e.g. timing of button presses, reaction intervals, physiological responses) and **physical** variables from the device (e.g. RNG bit patterns, electronic fluctuations) were recorded simultaneously. Lucadou then computed an exhaustive matrix of all possible variable pairs and counted how many pairs showed significant correlation. This method tests for the presence of **structure in the data as a whole** rather than a single observable effect research.ed.ac.uk psi-encyclopedia.spr.ac.uk.

The results were striking: during meaningful **experimental sessions** (where a participant was intending for "something" to happen), the data contained **roughly twice as many** significant inter-variable correlations as found in control sessions psi-encyclopedia.spr.ac.uk. In one analysis, the odds against chance were on the order of a million to one (about 5.5 sigma, $p \sim 10^{-6}$) psi-encyclopedia.spr.ac.uk. In other words: **structure and order spontaneously arose** in the multivariate data when a conscious observer was engaged with the system, even though no single measure on its own showed any anomaly. This fulfills MPI's prediction of non-causal but meaningful coordination: the participant and machine became entwined in an **entangled state**, manifesting as coherent correlations that **could not be used to send a message** (since their distribution was scattered across many channels). Lucadou interpreted this as evidence for "**non-transmissible**" psi – an entanglement-like coupling consistent with the MPI axiom that psi effects cannot violate information conservation psi-encyclopedia.spr.ac.uk.

Lucadou and colleagues refined the CMM protocol through the 1990s, simplifying variables and tightening controls. Psychological outputs were reduced to simple measures like counts or timing of button presses, and physical outputs included well-calibrated indices of RNG randomness (e.g. variance, autocorrelation) psi-encyclopedia.spr.ac.uk. The anomalous correlation effect persisted under these improved conditions psi-encyclopedia.spr.ac.uk. By the 2000s, Lucadou reported a series of CMM experiments (about a dozen in total) in which **nearly every study showed an excess of correlations beyond chance** psi-encyclopedia.spr.ac.uk. Such consistency is unusual in parapsychology – typically only 20–40% of studies in a given area are significant – suggesting this approach was capturing a reliable if subtle phenomenon psi-encyclopedia.spr.ac.uk.

Field RNG Studies and Group Coherence

Around the same time, other researchers were finding converging evidence in real-world settings. The **PEAR lab** at Princeton pioneered so-called **FieldREG** experiments in the 1990s, deploying portable RNG devices to locations of heightened group focus or emotion. For example, RNGs would quietly run in the background during **theatre performances, religious ceremonies, sports matches**, or even at mass gatherings like the Olympic Games and funerals. The question: would the randomness of these devices be affected simply by being present amid a **coherent group experience**? According to MPI (though it hadn't been formulated yet in PEAR's early days), a group of people sharing attention and emotion might form a temporary "closed" system of high meaning, in which mind-matter correlations could flourish.

PEAR's field RNG studies did find small deviations: the machines' output variance tended to depart from expectation **during the focused event periods** compared to before or after en.wikipedia.org. No single event was overwhelmingly convincing, but over many trials the pattern was detectable. This line of inquiry eventually expanded into the **Global Consciousness Project (GCP)**, an international network of dozens of RNGs continually monitoring world events en.wikipedia.org. The

GCP amassed data during globally engaging events (New Year's celebrations, terror attacks, big sporting events, etc.), testing whether collective attention correlates with statistical structure in random data. After 17 years and 500 formal events, the GCP's composite result was highly significant (overall $Z \approx 7.3$, corresponding to $p \sim 10^{-13}$) journals.lub.lu.se. In practical terms, this suggests that when millions of people's minds were **harmoniously engaged** by the same event, the network of random devices exhibited an **imperceptible but real** shift toward order. The magnitude of effect was tiny – on the order of a few parts in a million – yet over huge datasets it reached a 7-sigma deviation from null.

From an MPI perspective, these field results are exactly what one would expect: **collective meaning** (a crowd sharing emotions or attention) can create transient entanglement-like links among the people and any random systems in their environment. The result is a **weak, acausal covariance** that can only be seen by aggregating many random outputs. Notably, the investigators could not use GCP data to *predict* events or transmit signals – the effects only emerge retrospectively from statistical analysis, and often “spread out” in time around the focal event en.wikipedia.org. This aligns with MPI's **non-causal** stance. Lucadou himself has pointed to the GCP and field-RNG findings as illustrations of MPI's mechanism: when a group or situation is imbued with shared meaning (akin to a ritual or coherent consciousness state), **randomness becomes ever so slightly less random** across the system gowyrd.org.

*(It should be noted that alternative interpretations exist. For example, some analysts argue GCP results could be due to margin-of-error fluctuations plus selective interpretation en.wikipedia.org. The data are openly available, and debate continues over whether “global consciousness” or subtle biases better explain the correlations. Regardless, the **empirical fact** of tiny deviations in random data during meaningful events is well documented – even critics acknowledge the patterns, while disputing their cause.)*

Independent Replications and Extensions

One strength of the MPI evidence base is that **independent laboratories** have replicated the core findings using new participants and apparatus. Over the past two decades, researchers in different countries have attempted CMM-style studies and related dual-RNG experiments. A few notable examples:

- **Hartmut Grote (2019, Max Planck Institute)** – Grote, a physicist working on gravitational wave detection, carried out a rigorous **blind replication** of Lucadou's correlation matrix experiment [scribd.com](https://www.scribd.com). Using newly built hardware and software, he tested ~200 volunteers each trying to influence a quantum random process for about 30 minutes [scribd.com](https://www.scribd.com). The analysis plan was pre-registered and kept *blind* (the key data were hidden or permuted until final reveal to prevent any bias [scribd.com](https://www.scribd.com)). The outcome showed a **small excess of significant correlations** in the experimental data compared to shuffled-control data, with an overall $p \approx 0.02$ in favor of an anomaly psi-encyclopedia.spr.ac.uk. While not as dramatic as Lucadou's original results, it was a noteworthy confirmation that **something beyond chance** was occurring under MPI-like conditions, in a completely independent setup. (Grote's experiment also underscored how small these effects are – hundreds of people and many variables barely yielded a 2% significance level, a reminder of the delicate nature of psi phenomena.)
- **Edinburgh Koestler Parapsychology Unit (2000s)** – A series of PhD projects at the University of Edinburgh attempted to replicate the CMM findings psi-encyclopedia.spr.ac.uk. Across **five experiments** (with on the order of tens of participants contributing hundreds of sessions total), **four** showed the predicted surplus of correlations in the instructed condition. The combined probability of the overall effect was around $p \sim 0.001$, according to reports psi-encyclopedia.spr.ac.uk. These studies, supervised in part by Prof. Harald Walach and others, introduced stricter controls (e.g. permutation analyses to ensure no spurious positives). The fact that multiple experiments in a new lab **converged the same outcome** gave added credibility to the CMM paradigm. It suggested t

result wasn't a one-off fluke or quirk of Lucadou's equipment, but a genuine, if elusive, effect that others could observe with careful methodology.

- **Wolfhardt Janu (2023–24, Austria)** – Engineer and consciousness researcher
Wolfhardt Janu extended MPI research into more naturalistic **ritual settings**. He developed a system using **twin random number generators** running in parallel, and analyzed the moment-to-moment correlation between the two streams gowyrd.org. The setup was deployed during **tantric and meditative group sessions**, where participants engaged in intense emotional or spiritual practice. According to informal reports, Janu found that at certain peak moments – for instance, during synchronized breathing, chant, or emotional climax of a ritual – the two RNG outputs would briefly become **unusually correlated**, deviating from randomness together. Once the peak passed, the correlation subsided. These “entanglement correlation” spikes, while anecdotal in this context, are exactly what MPI would predict: high meaning and shared focus yielding a transient **ordering** between independent systems. (Janu's work directly inspired later commercial devices like Wyrd's “Wyrdoscope,” and his software became a foundation for those tools gowyrd.org.)
- **Wyrd Technology & Contemporary Studies (2020s)** – Building on prior work, the startup Wyrd Technologies has been conducting open-science experiments with **dual RNG devices** at group events. Their portable kit (the **Wyrdoscope**) contains two independent hardware random generators and monitors the correlation between them in real time gowyrd.org. Trials have been run at **mass meditation sessions, personal development workshops, and conferences** (e.g. the Integral European Conference 2025). In preliminary results shared by Wyrd, the RNG plots show brief surges of correlation during moments of **collective intention or emotion**, much like Wolfhardt Janu observed. In one analysis, a spike in synchronicity was so pronounced that the chance probability was quoted as less than 1 in 200,000 ($p < 5 \times 10^{-6}$) for that moment gowyrd.org. Such results remain tentative until formally published, but they mirror the earlier findings and have the advantage of being recorded under **preregistered, crowd-sourced conditions**.

Wyrd's efforts represent a modern, transparent approach to testing MPI: if numerous setups around the world all detect slight correlation increases during agreed-upon focus periods, it would greatly strengthen the empirical case for the model.

Together, these independent investigations form a modest but consistent empirical line. The **common theme** is that when humans enter a state of **heightened coherence, shared meaning, or focused intention**, random systems in their vicinity (or coupled them in an experiment) exhibit **tiny deviations from expectation**. No one replication is definitive – the effects are small and sometimes only marginally significant – but across many studies we keep seeing **glimpses of order in randomness** that coincide with meaningful engagement. This accumulation of consistent anomalies across laboratories and decades is what gives MPI a foothold as a viable model.

Meta-Patterns in Psi Phenomena

MPI was originally devised in large part to explain not just isolated experiments, but the **bigger picture** of parapsychology results – the puzzling “patterns of inconsistency” that have plagued the field. Intriguingly, many of these meta-patterns have been observed empirically, and MPI offers an elegant interpretation for them:

- **Decline Effects:** As noted, a decline in effect size over time is one of the oldest observations in psi research. From Rhine's dice-throwing trials in the 1930s (which showed a steep quarter-by-quarter decline in hits) psi-encyclopedia.spr.ac.uk, to card-guessing ESP tests, to modern ganzfeld telepathy sessions, researchers often find that the strongest outcomes occur early or by chance, and then subsequent attempts regress toward chance. MPI accounts for this by treating psi information as **pragmatic and finite** – once it “achieves its purpose” or is incorporated into the system's knowledge, it dissipates. A successful run inherently changes the experimental situation (e.g. the subject's confidence, the novelty, the experimenter's attitude), thereby altering the conditions and undermining repetition. The **failure to get sustained runs** of

significance is thus not a bug but a feature: the system self-stabilizes to prevent persistent signal transmission psi-encyclopedia.spr.ac.uk.

- **Evasion under Scrutiny (the Observer Effect):** A frequently reported issue is that gifted psi subjects or strong effects **disappear under too much scrutiny**. Tightening controls, adding observers or cameras, or otherwise increasing external observation tends to “collapse” the phenomenon. In MPI terms, this happens because the **organizational closure breaks down** – the participant is no longer in a closed, meaningful interaction loop, but is now being treated as an object of study from outside. This exo-observation injects an unrelated context (often one of skepticism or tension) that effectively decoheres the entangled state. The result: the previously observed psi effect **cannot manifest** in the new conditions psi-encyclopedia.spr.ac.uk. This mirrors certain interpretations in quantum physics where measurement can destroy an entangled state. MPI formalizes it for psychological systems: a psi conducive setup cannot survive aggressive dissection by an outside observer.
- **Small, persistent global effects:** As the field RNG and GCP studies indicated, psi effects on the macro-scale (involving many minds and many locations) tend to be **very small but statistically robust**. Meta-analyses of these global experiments suggest something real is happening, yet it remains tiny and elusive (the GCP’s overall result corresponds to an effect size on the order of $r \sim 0.001$) journals.lub.lu.se. MPI comfortably embraces this. In fact, it predicts that any **large-scale collective psi** would manifest only as a faint correlation, spread thin over many random systems – exactly what is seen. Moreover, these global effects obey the “**non-transmission**” rule: they have never been harnessed to predict events or send messages, only to retrospectively make statistical assertions (e.g. “something interesting happened at time X”) en.wikipedia.org. This non-utilizability is precisely why MPI stands out: it is one of the few theories that *expect* psi to be real **and** intrinsically hard to use, thereby fitting the empirical record.

In summary, phenomena like decline, replicability issues, the “shyness” of psi, and minuscule global effects are often viewed as problems or evidence against psi. MPI turns them around, asserting these are **natural consequences** of psi being an entanglement-like correlation. The empirical patterns across decades of research align with this view – an encouraging sign that we are on the right track to understanding psi on its own terms, rather than as a conventional force.

Effect Size, Scale, and Statistical Significance

It must be emphasized that the **effect sizes in MPI-related experiments are consistently tiny**. Whether it’s a correlation between two RNGs, or an excess of significant pairings in a matrix, or a shift in an event-driven RNG output, the deviations from chance are on the order of a few **hundredths of a percent**. For example, in dual-RNG studies the linear correlation coefficients might be $r \approx 0.01$ – practically negligible in any single instance. Likewise, the CMM studies don’t produce obvious hits or dramatic odds in one session; it’s only when you aggregate many correlations or many sessions that a significant excess emerges.

This point is crucial for interpreting the empirical support for MPI. These are **weak effects** by conventional standards, yet they are **highly replicable in aggregate**. By collecting enormous numbers of trials, or repeating sessions over months, research has achieved very high statistical significance out of the noise. The Global Consciousness Project accumulating **trillions of bits** of data to reach 7σ is one illustration journals.lub.lu.se. Lucadou’s experiments finding 30+ significant correlations out of hundreds of tested pairs is another psi-encyclopedia.spr.ac.uk. The picture that emerges is akin to a long-term stock market signal: invisible day-to-day but noticeable as a trend over time.

Importantly, **no experiment has ever extracted a clear, repeatable signal from these effects**. You cannot, say, look at an RNG in real time and discern that “people are meditating now” or transmit a yes/no bit through sheer intention. Every meaningful result has been **post hoc** – discovered by analyzing data after the fact. This aligns with

MPI's insistence that psi is **informationally sterile** (no usable communication) even though it's **real**. In fact, the moment someone *could* use an effect predictably, it would violate the nonlocal correlation model and collapse (much as a measured entangled particle yields no further spooky action). That paradoxical constraint – *psi can influence outcomes but you can't bottle it* – is exactly what we see in the lab. It's a big reason why skeptics remain unconvinced, but from MPI's vantage point, the **absence of a controllable signal is itself a confirmation** that we are dealing with entanglement-phenomena and not a new energy or force psi-encyclopedia.spr.ac.uk.

To put numbers on it: many MPI-type studies report results with z-scores in the rar of 1–3 for individual experiments (often corresponding to *p* values like 0.1 to 0.01). These wouldn't turn heads in most fields. However, when you pool repeated experiments or conduct meta-analyses, the combined *z* can reach 5, 6, or 7 – indicating extremely low odds of chance. For instance, the meta-analysis of five Edinburgh CN studies yielded an overall *p* ~0.001 psi-encyclopedia.spr.ac.uk, and Lucadou's 10+ experiment summary was on the order of *p* ~10⁻⁹ cumulatively psi-encyclopedia.spr.ac.uk. The lesson is that **MPI effects are statistically robust, but only when viewed in bulk**. Any single test is at risk of being a fluke in either direction (significant or null), which again ties back to the model's expectation that psi is **evanescent and context-dependent**.

Skeptical and Alternative Interpretations

It's worth acknowledging the views from outside (and within) the parapsychological community regarding these findings. **Skeptics** grant that experiments like the CMM or GCP are performed with commendable rigor, but they question whether the observed correlations might be explained by mundane factors. For example, there could be subtle biases in data selection or analysis – essentially a form of “**pattern matching**” or **multiple comparisons** that inflate significance en.wikipedia.org. In the case of the GCP, critics pointed out that with so many events and many ways to slice the data, one can sometimes find apparent spikes that **aren't truly tied to the event**

(for instance, choosing an “optimal” time window after the fact) en.wikipedia.org. Reanalyses of high-profile cases like 9/11 have cast doubt on initial claims of RNG anomalies for those specific events en.wikipedia.org. The skeptics’ argument is that **the data may be real, but the interpretation as psi is not justified** – instead it could be a statistical artifact or some unnoticed environmental influence on the hardware.

Even among researchers open to psi, MPI’s claims spark debate. Some parapsychologists favor **alternative models** (such as “weak signal + noise” models or quantum collapse theories) and are not fully sold that nonlocal correlations are the whole story. They acknowledge the empirical patterns – decline effects, elusive results etc. – but ask whether those could also arise from psychological factors (like declining motivation) or subtle **methodological issues** (like incremental changes in procedure over time) without invoking entanglement. The **interpretation** of the correlations is thus the key question: MPI says *acausal connection*, whereas a skeptic might say *hidden causal variable*. For instance, could participants inadvertently be influencing the equipment via microforces or experimenters unconsciously biasing the data? Researchers try to rule these out (e.g. using automation, shields, random protocol decisions), but the door is not completely closed.

Notably, **no conventional explanation has managed to account for all the meta-patterns simultaneously**. This is why MPI still has traction: it provides a single coherent explanation for the **presence of weak correlations** and the **absence of strong signals**. Skeptics tend to dismiss the whole lot (weak correlations = probably nothing) while MPI proponents accept the correlations as real but constrained. The empirical stance at present is cautious optimism – enough independent work has shown effects that something is there, yet it remains “**on the margins of detectability**.” As an evaluator from *The Age* quipped about the GCP, the evidence isn’t solid enough to shout “global consciousness” from the rooftops en.wikipedia.org. However, the data also refuse to disappear entirely, as one might expect if there truly was nothing but noise. MPI sits in that uncomfortable middle, and its supporters would argue that t

discomfort is alleviated once we accept psi on its own terms: it's real, but operates more like a fleeting relationship than a broadcast signal.

Current and Upcoming Tests

Research inspired by MPI is ongoing, with a trend toward greater transparency, larger sample sizes, and cross-lab collaboration. A prime example is the planned **Wyrdoscope Replication Project (2025–26)**, which aims to be the most stringent test of MPI to date. In this project, multiple teams across different locations will run identical dual-RNG setups during coordinated **group meditation sessions** and similar events. All protocols are preregistered (deciding in advance how and when data will be collected and analyzed), and the data will be pooled openly. The primary prediction is straightforward: when a large group enters a synchronized, meaningful mental state (e.g. a guided meditation focusing on compassion at a scheduled time), the two random streams at each site will show a slight but measurable **positive correlation** during that window, more so than during control periods with no specific group focus. Because each node uses independent quantum-based RNGs gowyrd.org, any coincident fluctuations between them should not occur *unless* something like a nonlocal influence is at work.

If this multi-site experiment finds a significant effect, it would mark a milestone for MPI. Firstly, it would demonstrate psi correlations **on demand** (**albeit statistically**) under full scrutiny – a strong rebuttal to the idea that such effects are always “fluky” and confined to one lab. Secondly, the open-data, many-lab approach would make it hard to attribute the result to artifact: with identical devices running in unconnected locations, ordinary environmental influences would average out. And thirdly, it would provide a rich dataset to examine MPI's finer points: for example, one could see if the effect is bigger in sessions rated as more **emotionally coherent** or whether it **declines** across repeated sessions (testing that pragmatic information “use-up” directly). In short, the community is moving toward experiments that not only *seek* evidence for MPI, but also *challenge* its limits. Either outcome – a clear replication or a clear null

will be highly informative. As of 2025, early trials are underway, and the research teams (comprised of both believers and skeptics in the mix) are eager to see if the correlations can reliably materialize from the “consciousness field” on cue [gowyrd.c](#)

Timeline of Key Experiments (1970s–2025)

To put the empirical development of MPI in perspective, the table below highlights **major experimental milestones** over the past decades, along with their scale and outcomes:

Period	Researchers / Lab	Experiment & Sample	Key Result
--------	-------------------	---------------------	------------

1970s	Helmut Schmidt, J. B. Rhine, et al.	Early RNG-PK trials (automated coin flips and electronic RNGs). Typical N: tens of thousands of trials.	Small biases observed in random outputs, but effects declined or vanished upon repetition psi-encyclopedia.spr.ac.uk . Laid groundwork by highlighting the <i>elusive, diminishing</i> nature of psi effects.
-------	-------------------------------------	---	--

1980s–90s	Walter von Lucadou (IGPP, Freiburg)	Correlation Matrix Method (CMM) Multi-variable RNG experiments. Dozens of sessions with ~40+ variables recorded per session research.ed.ac.uk research.ed.ac.uk . Excess correlations observed in meaningful sessions (~2× more than controls) psi-encyclopedia.spr.ac.uk . Huge initial effect size (5.5σ , $p \sim 10^{-6}$) indicating emergent structure without causal signals.
-----------	-------------------------------------	---

1990s	PEAR Lab (Princeton) and collaborators	FieldREG : RNGs placed in group settings (meditations, concerts, sports, etc.); ~100s–1000s of trials per event.	
Global Consciousness Project (1998–2015) : Network of 50–70 RNGs worldwide logging continuous data (trillions of bits). Small departures from randomness during group events. FieldREG replications yielded composite chance odds $\sim 10^{-4}$ en.wikipedia.org . GCP’s 17-year dataset showed an overall deviation of $Z = 7.3$ ($\approx 5 \times 10^{-13}$ probability) journals.lub.lu.se , suggesting a weak but global mind-matter effect.			

2000s Harald Walach; Koestler Parapsychology Unit (Edinburgh) **Independent CM replications:** 5 studies (in Freiburg and Edinburgh) totaling ~400 experimental sessions. [research.ed.ac.uk](https://www.research.ed.ac.uk) [research.ed.ac.uk](https://www.research.ed.ac.uk). Permutation analyses used for control. 4 of 5 studies positive (excess psi correlations); combined significance $\sim 10^{-3}$ psi-encyclopedia.spr.ac.uk. Effect persisted with different RNG devices and under strict protocols, supporting cross-lab robustness.

2010s Hartmut Grote (Max Planck Institute, Hannover) **Blind CMM experiment:** ~100 participants, each ~30 min session influencing a quantum RNG [scribd.com](https://www.scribd.com) [scribd.com](https://www.scribd.com). Pre-registered “blind” analysis (no peeking until end). **Modest correlation surplus** found in experimental data (reported $p \approx 0.02$) psi-encyclopedia.spr.ac.uk. While not highly significant, it confirmed the general trend with new hardware and ruled out analytical biases (due to the strictly blind procedure).

2020s Wolfhard Janu (Austria); Wyrd Tech (Intl. collaboration) **Dual-RNG “Entanglement” tests:** Two independent RNGs run in parallel during rituals and group meditations. Sample: multiple sessions with 2× RNG streams (1 bit/sec each). **Wyrdoscope multi-site studies:** Ongoing (2025) with synchronized RNG pairs at events, open-data approach. **Transient RNG correlations** recorded during peak emotional/mental coherence. For example, Janu’s tantra sessions showed brief spikes where RNG outputs synced beyond chance gowyrd.org. Similarly, Wyrd reports zero lag correlation bursts during group focus (one event had odds <1:200,000 of being chance) gowyrd.org. A large pre-registered replication is in progress to confirm the effects on a broader scale.

(Sources: See referenced lines for details of each entry. Not all results are published in peer-reviewed form; some derive from conference reports and project updates.)

Summary and Outlook

Over some 30+ years, empirical research consistent with MPI has **steadily accumulated**. The evidence is subtle but collectively significant: when human

consciousness engages in shared, meaningful activity, the normally random behavior of physical systems shows **tiny hints of order**. These hints never amount to a usable signal and often fade or “jump” to different metrics when we try to pin them down exactly as MPI predicts. In a sense, this line of investigation has turned the **limitations** of psi research into clues: the very factors that once made psi seem capricious (declines, inconsistency, lack of replication) are now hallmarks of an underlying entanglement-like process that **prohibits straightforward replication by its very nature** psi-encyclopedia.spr.ac.uk.

The current empirical status of MPI can be summarized as a **consistent pattern of inconsistency made coherent**. We see non-causal correlations, but no causal forces significant outcomes, but only in aggregate; effects that are real, but only manifest when nature’s “loopholes” (meaning and randomness) align just right. This is admittedly **frontier science**, sitting at the edge of what conventional models can accommodate. Skeptics rightly demand more data and better tests – and those tests now underway with modern tools. If upcoming multi-lab studies succeed, MPI will gain compelling support as a scientific account of psi. If they fail, MPI may need revision or scientists may conclude that simpler explanations (bias, wishful thinking) suffice after all.

Either way, Walter von Lucadou’s Model of Pragmatic Information has already made profound contribution: it **shifted the experimental focus** from chasing overt paranormal miracles to examining the delicate fabric of correlations that weave mind and matter together. In doing so, it has kept the door open for psi research in a form that doesn’t contradict physics, even as it extends our notion of information and meaning. The empirical journey is ongoing, but one thing is clear – wherever mind interacts with randomness under conditions of meaning, something *interesting* tends to happen. MPI is our guide to deciphering that mystery, one tiny correlation at a time.

Future Horizons: Experiments and Technologies Informed by MPI

Best Psi Experiments to Perform Under MPI

Designing psi experiments under the Model of Pragmatic Information calls for creative approaches that **preserve organizational closure, avoid direct signal trans and leverage contexts rich in meaning.** In practice, this means treating the experiment as a self-contained “entangled” system – participants, experimenters, and

devices form a closed loop bound by shared intent and symbolism gowyrd.org. **Any attempt to force a signal or overt outcome is avoided**, since MPI predicts such instrumental aims will collapse the very correlations we seek gowyrd.org. Instead, researchers look for **spontaneous, acausal correlations** that emerge when the conditions are right psi-encyclopedia.spr.ac.uk. This approach has proven fruitful: Lucadou's famous correlation matrix experiments, for example, found **highly significant patterns of correlation** between human behavior and random data when no specific "hit" was demanded psi-encyclopedia.spr.ac.uk. By instructing participants to engage in a task (e.g. pressing buttons at will) without a fixed goal and then analyzing countless relationships among psychological and physical variables, these experiments revealed *more than twice as many correlations in experimental sessions as in controls* – a huge effect (on the order of $p \approx 10^{-6}$) psi-encyclopedia.spr.ac.uk. Crucial because no single measurement carried the weight of "proving" psi, the non-local entanglement could manifest as subtle structure in the data without violating MPI's No-Transmission principle. This correlational methodology has now been replicated multiple times, confirming that **psi thrives when we seek meaningful connections rather than straight-line causes** psi-encyclopedia.spr.ac.uk.

What kinds of studies best embody these principles? Researchers are now exploring environments and protocols that maximize meaningful coherence while minimizing any explicit "signal" intent. One promising strategy is deploying next-generation random event generators – sometimes playfully dubbed "**Wyrdoscopes**" – in situations where people collectively enter **heightened states of significance**. These devices, often containing dual quantum-based RNGs, measure emergent order in randomness by looking at correlations between two independent streams gowyrd.org. Notably, by using two synchronized RNG outputs and algorithmic window selection, the system gains many degrees of freedom; **patterns caused by simultaneous fluctuations can be detected automatically**, and this flexibility appears to **reduce the decline effect** that plagued repeat trials in earlier psi studies gowyrd.org gowyrd.org. In essence, the apparatus itself is part of the "meaning field" rather than an external meter – a direct application of MPI's insistence on *organizational closure*. Researchers report that with

this setup, the usual regression of psi effects is markedly attenuated gowyrd.org, presumably because each session stays novel and context-tied rather than becoming rote, exploitative test.

In line with these insights, a number of **forward-looking experiments** can be recommended:

- **Sacred and Ritual Settings:** Placing REG-based “wyrdosscopes” in **religious rituals, prayer gatherings, and sacred sites**. Historical field studies (the *FieldRI* experiments) already found that portable RNGs showed anomalous deviations during coherent group events – from church rituals to theater performances en.wikipedia.org. By logging random outputs quietly in the background of a **pilgrimage, temple ceremony, or indigenous healing ritual**, researchers can later analyze whether the RNG streams became subtly correlated during peak moments of collective reverence or emotion. The expectation (per MPI) is that when the group forms a genuine closed loop of shared meaning, **the devices will register improbable structure in their randomness** – not as a message, but as a kind of sympathetic resonance with the ritual gowyrd.org gowyrd.org. Any such correlations would be detected post hoc (using methods like correlation matrix or Fourier analyses) rather than in real-time, preserving the unselfconscious nature of the event.
- **Group Meditation and Collective Intention:** Deploying entanglement sensors at **mass meditation gatherings, mindfulness retreats, or collective intention ceremonies**. Intense group coherence is a fertile ground for non-local correlations; for example, when hundreds or thousands of people meditate together with a shared peaceful intent, one can treat the entire assembly plus measuring devices as a single system. Pioneering studies like the Global Consciousness Project found that worldwide networks of RNGs became slightly less random during **globally synchronized meditations and major emotional events**, as if picking up on a common “field” en.wikipedia.org en.wikipedia.org. Building on this, researchers now suggest using portable RNG units (or wearable entropy sensors) in group

meditation halls to detect **fluctuations in ambient randomness during periods deep collective calm** or heart-focused intention. The **Wyrd technology** has already demonstrated real-time feedback in such contexts – for instance, at the Integra European Conference 2025 a Wyrdoscope showed a dramatic spike in order (od $\ll 1$ in 200,000 by chance) when a large group meditation reached an emotional “letting go” peak gowyrd.org. Recommendations for these experiments emphasize that participants not be told to “try to affect the machine”; instead, **they immerse in the meditation**, and any device quietly logs data in the background gowyrd.org. Only afterward do analysts correlate the data with the event timeline (e.g. synchronized breathing periods, mantra chanting, etc.), using tools like **Correlation Matrix Analysis** to spot patterns.

- **Altered-State Therapies and Psychedelic Sessions:** Introducing RNG monitoring in **psychedelic-assisted therapy rooms, shamanic ceremonies, or entheogenic retreats**. These settings produce intense subjective meaning – patients or participants often report feelings of unity, presence of “energies,” or synchronicities while in non-ordinary states of consciousness. According to M, such **emotionally and symbolically rich microcosms** could foster mind-matter entanglements. A conceivable experiment might place a hidden quantum random generator (or a pair of them, for correlation detection) in an ayahuasca circle or psilocybin therapy session. The device would passively collect random data throughout the session. Researchers would later examine if significant deviation or correlations emerged during moments like group prayer, peak catharsis, or healer-led songs. Since these sessions already treat the space as sacred and the **participants form a closed, trusting group**, any anomalous order in the randomness would strengthen the case that *meaningful shared experience can imprint on physical systems*. Indeed, early work by Wolfhard Janu found that **twin REGs showed strong correlated fluctuations during tantra rituals** involving deep interpersonal connection gowyrd.org – a striking hint that altered states and conscious resonance can register physically.

- **Healing Circles and Energy Medicine:** Using portable entanglement detectors **Reiki circles, Qigong groups, prayer healing meetings, or other energy medicine sessions.** Here the hypothesis is that when healers and subjects enter a focused compassionate state (often intending the flow of some “subtle energy”), the structured group intention might coincide with statistical structure in ambient random processes. A “Wyrdoscope” could sit in the room as people practice healing touch or send intentions, without any direct interaction from them. The absence of a directed task avoids violating the Non-Transmission axiom; instead of trying to send a healing “signal” to the machine, **the group simply maintain field of meaning**, and any machine anomalies are a side-effect of that field. Over multiple sessions, one could apply **passive anomaly detection** algorithms to see, say, instances of reported successful healings correlate with spikes in RNG coherence. **MPI predicts micro-effects** rather than miraculous leaps – e.g. tiny decreases in entropy that align with the most intense healing moments – but across many trials such patterns can accumulate into strong evidence that mind and matter were briefly entwined.
- **High-Emotion Collective Events:** Studying **mass gatherings charged with emotion**, such as peace protests, vigils, festivals, or even concerts and sports finals. Whenever large groups share a synchronized emotional experience (whether sorrow, joy, excitement, or determination), MPI would consider the crowd-plus-environment a candidate for transient entanglement. FieldREG studies from the Princeton PEAR lab already hinted at this: RNG devices taken **sports events and theater performances** showed unlikely deviations exactly during climactic moments of audience engagement en.wikipedia.org. The best experiments now would be to refine and repeat these tests with modern hardware. For instance, a network of time-synchronized RNGs could be placed around the venue of a major event (a championship game or a mass rally) and set to record continuously. Researchers would look for **concurrent shifts across the RNG network** during peak crowd reactions – a signature of a collective “field effect” rather than local noise en.wikipedia.org. Thanks to advanced

algorithms, this can be done in a blind, data-driven manner (no cherry-picking intervals gowyrd.org): software can identify when multi-RNG variance diverged from expectation, and only then is the event timeline consulted to see if a meaningful crowd experience occurred at those moments. A convergence would support the idea that intense shared emotion increases entanglement-like correlations in physical systems.

- **Liminal and “Haunted” Locations:** Installing sensitive RNG devices in **places long associated with anomalies** – for example, reputed haunted houses, ancient sacred groves, or “thin places” in folklore – especially during times when visitors engage in rituals or investigations. The rationale is that such locales may already carry layers of meaning and expectation, forming an implicit observer system of legend, belief, and environment. Under MPI, *context is everything*. If people go to a famously haunted castle and hold a séance, the entire situation is rife with narrative meaning and emotional tension – fertile ground for pragmatic information flow. A well-designed experiment might conceal multiple RNGs (or other entropy sensors like photon detectors) in the site and let them run for extended periods, while various groups conduct their vigils or ceremonies. Rather than chasing any specific ghostly signal, researchers would later aggregate the data to see if statistically unlikely correlations emerged at times of heightened engagement (e.g. a midnight vigil on the castle’s anniversary). **Previous work has indeed found hints of structure in random outputs at liminal sites** – one example being subtle anomalies detected at ancient stone circles during seasonal ceremonies (as reported anecdotally in paranormal research communities). By approaching these investigations *non-confrontationally* (i.e. not trying to prove a haunt, just observing correlations), scientists stay within MPI’s safe zone of non-intrusive measurement. Any positive findings would suggest that human consciousness interacting with charged locales can imprint measurable order on randomness – essentially a **modern take on synchronicity in place**.
- **Remote Viewing with Entangled Devices:** Pushing the envelope, one could pair remote viewing experiments with entanglement-based monitoring. Remote

viewing (clairvoyantly describing distant targets) has a mixed history of success but under MPI one might reconceptualize it: not as “information transmission” but as establishing a temporary entangled system between viewer, target, and experimenter. A novel protocol might involve an AI-curated target pool and an RNG-based feedback system. For instance, while a viewer attempts to describe hidden target image, a network of RNGs runs quietly in both the viewer’s location and perhaps at the target site or a control site. The goal is not to see if the viewer can send a clear message, but to see if **correlations increase between the random outputs** at the two locations or between the RNG at the viewing site and the accuracy of the description. By using an AI to evaluate the similarity of the viewer’s description to the target (thus avoiding human bias) and correlating this with any RNG anomalies, one could detect a triadic entanglement: viewer consciousness, target information, and random physical systems momentarily linked. This would extend Lucadou’s correlation matrix idea to psi perception; success would be indicated not necessarily by perfect target description, but by **non-local patterns** (e.g. the RNGs deviating in sync when the target is correctly “felt”). Such context-aware experimentation keeps with MPI’s dictum that **meaningful configurations can arise holistically, even if no one piece carries a usable signal** gowyrd.org.

Across all these experiments, certain **best practices** emerge. First, the **use of passive monitoring and blind analysis** (as opposed to real-time feedback demanding a result) is key. Participants should not consciously try to “make something happen”; they engage in the experience for its own sake. The measuring devices, in turn, operate like *Easter eggs* hidden in the environment – part of the scenery, not the focus. **Correlation-centric data analysis** then allows the research team to detect any psi effects without violating the No-Transmission axiom. Second, it’s essential to **maintain novelty and adaptive protocols**. MPI suggests that if an experiment is repeated identically ad nauseam, pragmatic information is used up and effects will fade gowyrd.org. To counter this, experiments can incorporate variation and unpredictability: change the location, alternate the type of group activity, or even use

algorithmically random start times for data collection gowyrd.org. This keeps the overall system from becoming too rigid or preconditioned, thereby preserving the *autonomy* (A) term in Lucadou's formulation (ensuring we get some surprising outcomes even if it costs us in consistency). Finally, researchers are encouraged to cultivate an **aesthetic or reverential approach** to the study – treating each trial as a unique “encounter” with the psi phenomenon rather than a factory-floor test. The Wyrd research team explicitly advises event facilitators to “**let go of control and in the mystery**” gowyrd.org, meaning one should set the stage for coherence but then trust something emergent (and unpredictable) to manifest. In practical terms, this might include beginning an experiment with a brief ritual (to symbolically **include a device in the circle** and affirm that everyone is “in this together” gowyrd.org gowyrd.org) and ending with a closure ritual. Such practices reinforce the **organism unity of the system**, which MPI posits is the very condition that allows psi correlations to flourish gowyrd.org. By contrast, if one were to treat the technology an outside instrument or constantly scrutinize it during the session, the fragile entanglement could decohere (an “exo-system collapse” in effect). In sum, the best MPI-aligned experiments are those that **blur the line between observer and observed** making the experiment *a shared meaningful experience* first – and a data-gathering exercise only second. Under those gentle conditions, psi's “firefly” can dance.

Influencing Skepticism and Shifting Acceptance: While MPI discourages chasing dramatic one-off proof of psi to “convert” skeptics, it does provide a more resilient path for winning scientific openness in the long run. Paradoxically, by **not** trying to transmit a blatant paranormal signal (which MPI says is fundamentally forbidden psi-encyclopedia.spr.ac.uk), researchers can accumulate subtle but **replicable** findings that are harder to dismiss. For example, the correlational matrix experiments not only produced huge effects in single studies (one with $p \sim 10^{-6}$ psi-encyclopedia.spr.ac.uk) but they have been independently replicated multiple times under stringent conditions psi-encyclopedia.spr.ac.uk. *Different teams using varied hardware and methods all found the same excess of correlations in psi conditions*, including a PhD project that successfully repeated the result five times psi-encyclopedia.spr.ac.uk. Even a mainstream physicist

at the Max Planck Institute tested this paradigm, finding significant mind-matter correlations in one trial psi-encyclopedia.spr.ac.uk, and Lucadou reports that nearly of ten strict replications showed above-chance structure in the data psi-encyclopedia.spr.ac.uk. This kind of **cumulative evidence**, obtained via pre-register designs and blind analytics, directly addresses common skeptical criticisms about f drawer effects or fluke results. In fact, a recent replication attempt was published openly with a null outcome – after an error was discovered in the original data – demonstrating the field’s commitment to transparency and learning from failure researchgate.net. Such methodological rigor and honesty make the remaining positive findings **that much more credible**.

Equally important, the MPI framework lowers the theoretical barriers for skeptics. One classic objection has been that accepting psi would “*overturn the laws of science*.” But MPI’s no-signal model neatly **avoids violating known physics**: no new energy or forces are invoked, only non-local correlations analogous to quantum entanglement psi-encyclopedia.spr.ac.uk. In other words, scientists need not reject established physics to countenance psi; they only need to **expand** their concept of information systems to include entangled mind-matter states psi-encyclopedia.spr.ac.uk psi-encyclopedia.spr.ac.uk. This makes psi far more palatable as a legitimate subject of inquiry, since it fits as an *extension* of modern science rather than an anomaly. Over time, as rigorous MPI-aligned studies continue to yield consistent if subtle results, they can **erode the wall of skepticism** by scientific merit alone. The goal here isn’t to “convert” doubters with a single headline-making stunt – an approach that history shows usually backfires – but to **build an empirical foundation** so solid that the wider scientific community can’t help but take notice. In short, by focusing on doing good science (instead of winning arguments), MPI researchers may ironically end up *moving the needle* of acceptance more effectively: the evidence speaks for itself, and even hardened skeptics have less to grab onto when experiments are theory-backed psi-encyclopedia.spr.ac.uk, meticulously run, and reproducible psi-encyclopedia.spr.ac.uk psi-encyclopedia.spr.ac.uk. Ultimately, the **best way to be “skeptic-proof”** is to **embrace a better vision** – one that prizes understanding over proof. By pursuing ps

a genuine scientific mystery rather than a contested claim, MPI-based research creates a safe space for skeptics and proponents alike to **shift toward curiosity**, gradually normalizing psi as just another frontier of science that yields to careful exploration

Implications for Spirit Tech 3.0

The Model of Pragmatic Information doesn't just reframe experiments – it **reshape our vision of what spiritual technology can be**. In recent years, so-called “Spirit Tech” has seen two broad waves. **Spirit Tech 1.0 and 2.0** were characterized by tools like neurofeedback headsets, brain stimulation devices, or meditation apps that explicitly tried to induce altered states or accelerate personal growth. Their goal was often **causal transformation**: stimulate this brain region to spark calm, flash these visuals to ignite transcendence, etc. Under an MPI lens, however, much of this approach looks like trying to force a butterfly to land. **Spirit Tech 3.0**, by contrast, is emerging as a paradigm shift – *from pushing to listening, from intervention to attunement*. Instead of gadgets that impose a change on consciousness, the next generation of spiritual tech may function more like **entanglement amplifiers and meaning mirrors**, sensitively responding to the user's or group's state and highlighting naturally arising synchronies.

In practical terms, an MPI-informed Spirit Tech device would behave less like a deterministic machine and more like an **oracle or musical instrument**. Consider, for example, a future meditation platform that incorporates an RNG-based “synchronicity sensor.” Such a device wouldn't drive the meditation with stimuli, but would monitor the subtle coherence of the group and provide gentle feedback – perhaps a soft ambient glow or sound that **intensifies when collective brainwaves, heart rhythms, and random data streams come into sync**. The emphasis is on *revealing correlation*, not causing it. Early prototypes of this idea exist: the **Wyrd Light** is one such tool, a lantern that changes color and brightness in response to realtime randomness deviations gowyrd.org. In a dark meditation hall, a group might sit in silence and notice the Wyrd Light gently begin to glow in moments when everyone's mind “feels

especially unified – a wordless indication that something invisible is being shared. This kind of feedback doesn't tell anyone what to do (no one is pressing buttons or following prompts); it simply *reflects the emergent correlation* back to the participants gowyrd.org gowyrd.org. Used skillfully, such technology can help people develop a **subtler awareness** of their own consciousness and connection. It's more akin to a **synchrony barometer** than a traditional biofeedback device.

We can imagine several categories of Spirit Tech 3.0 devices and platforms:

- **Entanglement Amplifiers:** These are systems intentionally designed to **amplify the felt sense of interconnectedness** by leveraging psi correlations. They might combine sensors for group physiological coherence (heart rate variability, EEG etc.) with RNG-based entropy monitors. The device's role is to *amplify any spontaneous harmony* – for instance, if a dozen people chanting together produced an anomalous pattern in a random signal, the device might respond by projecting soothing visuals or resonant tones, thereby deepening the group's shared state. Importantly, the amplifier does not push the group into a state (as a drug or a brain stimulator would); it listens at multiple levels and *resonates* back the group's own emergent order. In theory, this creates a positive feedback loop of meaning: the more coherent and “entangled” the participants become, the stronger the feedback signal, which further encourages coherence. Because the feedback is based on *non-local correlations* (something the participants can't directly fake or force), it invites a **poetic, exploratory attitude** rather than a performance mindset. One could think of it as a high-tech campfire around which modern seekers gather – providing a focal point for collective consciousness, but dancing unpredictably in response to the group's subtle intentions.
- **Synchronicity Trackers:** Another frontier is personal technology that helps individuals recognize meaningful coincidences and patterns in their daily life – essentially a “tracker” for one's entanglement with the world. Imagine an AI-driven journal app that records not only your thoughts and emotions but also connects to an RNG running in the background of your phone. The app might

note, for example, that **whenever you enter a deeply reflective or prayerful state, the RNG shows brief departures from chance**. Over time, it could alert you to these correspondences, perhaps with a gentle notification like, *“In moments of insight, the surrounding field shifts.”* Similarly, a synchronicity tracker could integrate with calendars and sensors: if you and a close friend experience strikingly parallel moods or events on the same day, the system could flag this non-locally correlated occurrence (with your permission). The goal here isn’t to rationalize or databan every mystery, but to **nudge our awareness to the interconnected fabric of experience**. By quantifying some aspects of synchronicity (e.g. significant RNG spikes coincident with personally meaningful events), such tech might actually **legitimize the intuition** that our inner states and outer reality are entwined. This is a radical departure from the current “smart” tech ethos – it’s no longer about optimizing productivity or predicting consumer behavior, but about validating *acausal, meaningful* interplays that people typically notice only anecdotally. In essence, the device says: *“Yes, that meaningful coincidence you sensed may have been real – here is a trace in the data.”* The psychological impact of that validation can be profound, encouraging users to treat life events less as isolated incidents and more as part of a larger, entangled narrative.

- **Meaning Resonance Systems:** At the societal level, one can envision platforms that function as **real-time meaning resonance networks**. These could be digital infrastructures that support collective rituals, global meditations, or even decision-making processes by monitoring the *qualitative* coherence among participants. For example, consider a future conferencing system for distributed groups practicing social meditation. Everyone logs in from around the world; each participant’s local sensors (could be as simple as a browser-based RNG, or wearables tracking physiological calm) feed into a shared display that visualizes the group’s moment-to-moment entanglement. If the group enters a highly unified state of mind, the system might visibly reflect that – say, a mandala graphic that becomes more ordered or luminous. This not only provides feedback but also creates a sense of **shared sacred space** in digital form. Such a system could be u

for global synchronized prayer events, where instead of just seeing “number of people online,” participants see a representation of their **collective consciousness coherence**. In early form, the Global Consciousness Project hinted at this possibility by showing that distributed RNGs fluctuate during worldwide events en.wikipedia.org en.wikipedia.org. A next-gen platform could make this information immediate and interactive. Imagine a “global coherence dashboard” accessible to anyone: when a crisis or a celebratory event occurs, clusters of RNGs and other sensors around the world register the emotional outpouring, and people can literally watch a real-time graph of the *planetary noosphere* responding. This isn’t about control – it’s about cultivating a new kind of planetary awareness. Indeed, the **GCP 2.0 project** is already moving this direction, deploying clusters of 20 RNG devices in **25 major cities and sacred sites worldwide** to measure collective emotional effects heartmath.org heartmath.org, and inviting citizen participants to host devices and join synchronized meditations heartmath.org heartmath.org. One can easily imagine these networks evolving into a kind of “**global spirit platform**” that complements social media (which connects us through explicit messages) with an entanglement-based medium connecting us through shared meaning and intent.

Overall, **Spirit Tech 3.0 devices prioritize attunement over stimulation**. They are less like drugs and more like **mirrors or musical instruments** that respond to the psyche. This shift aligns perfectly with MPI’s core message: you cannot *push* consciousness non-locally, but you can *invite and ride* the correlations that emerge gowyrd.org gowyrd.org. The implications for design are significant. For one, developers of such tech must **embrace unpredictability and user co-creation**. An entanglement-based app, for instance, might not give the same “experience” every time – in fact, by design it shouldn’t, because it requires the fresh meaning of each context. This runs counter to typical product mindset where consistency is king. Yet, paradoxically, this opens the door to experiences of genuine awe and novelty for users. Imagine a digital oracle that occasionally produces an uncanny, deeply personal synchronicity – something no

linear algorithm could have planned. Those are the kinds of moments Spirit Tech 3. seeks to support.

There is also a reframing of **the role of the user**. Instead of being a consumer pushing buttons for a predefined outcome, the user (or practitioner) becomes a **participant in a living system with the tech**. For example, using an entanglement amplifier in a group meditation might feel less like using a gadget and more like engaging with a subtle presence in the room. In this sense, Spirit Tech devices may take on a quasi-ritual character. They might be beautifully crafted, symbolic objects (not just clinical instruments) that people treat with a kind of respect. One can envision, say, a “**digital altar**” device: a sculpture containing sensors and RNGs that sits at the center of a circle, quietly responding to the group’s prayer or song with illuminated patterns. Participants might even begin by acknowledging the device – essentially welcoming it as an **elemental witness to the circle** rather than a piece of lab equipment gowyrd.org. This harkens back to ancient practices with oracles and sacred tools, but updated in an empirically-grounded, transparent way.

The **cultural impact** of MPI-driven Spirit Tech could be significant. It offers a way to bridge the often separate realms of scientific gadgetry and soulful practice. If done right, these technologies will not be about “proving” spirituality or forcing enlightenment, but about **enriching practice**. For instance, a digitally supported group meditation that measures coherence isn’t there to rank participants or guarantee a mystical experience; rather, it serves as a gentle guide and storyteller of the session’s collective journey. Over time, using such tools could also **democratize psi and mysticism**, taking them out of the sole domain of gifted psychics or monks and into a space where groups of regular people can tangibly explore their latent connectedness. It shifts the focus from individual psychic *abilities* (which MPI tells us are fickle and non-repeatable on demand) to **collective psychic conditions** – states we cultivate together in which psi phenomena naturally bloom as *by-products*. Technology, surprisingly, can help by *holding space* for those conditions, much like a well-design

musical instrument holds the possibility of beautiful music which skilled players can evoke.

A final implication is that Spirit Tech 3.0 will likely foster a new mindset of **non-control in innovation**. Engineers and entrepreneurs working with these ideas will need to partner with artists, facilitators, and wisdom traditions, because designing emergence and meaning is fundamentally interdisciplinary. Already, we see collaborations forming: technologists are teaming up with meditation teachers, ritual leaders, and even AI ethicists to ensure these tools honor the depth of human experience. The **Spirit Tech sector**, according to some thought leaders, is at an inflection point where it must balance cutting-edge capabilities (like real-time sensor AI pattern recognition) with **ancient insight** into the soul's journey inclusiontree.com.au. MPI provides a theoretical backbone for this balance, reminding us that any genuine "spirit tech" will operate on *holistic, acausal principles* rather than just the push-button paradigm of conventional tech. In short, **MPI invites Spirit Tech to become more like a *partner* in spiritual growth than a mechanism for it** – an extension of our collective intuition and ritual, rather than a replacement for them. The reward, if we get it right, is not just cooler gadgets, but potentially a new **culture of communion** in which humans and our technologies jointly participate in the subdance of consciousness.

Implications for the Broader Study of Consciousness

Perhaps the most profound impact of the Model of Pragmatic Information is how it challenges the broader science of consciousness to **expand its framework beyond signals and neurons**, toward a view of mind as something fundamentally relational and non-local. Cognitive neuroscience and psychology have long operated on a transmission model: neurons fire electrical signals, brain regions communicate, and somehow out of that signaling arises the experience of being. MPI flips this narrative. It suggests that **meaning and consciousness might be woven through systems in ways that are not reducible to point-to-point signals at all**. In MPI (and GQT), even the

distinction between “mind here” and “matter there” becomes fluid – they can form entangled whole when linked by significant information gowyrd.org gowyrd.org. This poses a challenge to strictly materialist neuroscience: if some interactions in nature are *constitutively acausal* (formative but not forcing), then hunting only for causal chains in the brain could miss the essence of consciousness. After all, how do you locate meaning or intentionality in a neuron? MPI would argue that you don’t – you locate it in the *relations among neurons, person, environment, and beyond*. Consciousness might sit neatly inside the skull, but rather manifests in the **organizational closure of a person interacting with their world**. This resonates with certain trends in the philosophy of mind (e.g. enactivist and extended mind theories) and even analytic phenomenology, which emphasize that experience is not a passive brain “printout” but an active, context-bound process.

Going forward, the study of consciousness stands to benefit from MPI by **broadening its investigative lens**. Interdisciplinary collaboration will be essential. **Psi research** can no longer remain a fringe curiosity; it holds empirical data (however contentious) that any mature theory of consciousness must account for. Conversely, **neuroscience and complexity science** bring sophisticated methods that can be applied to psi data in new ways – for example, using network analysis to detect entanglement correlation or applying information theory to measure pragmatic information exchange. **Systems theory** is the natural meeting ground of these, providing concepts like feedback loops, self-organization, and emergence that are clearly needed to describe psi phenomena. Indeed MPI itself emerged from a systems perspective, and it encourages mainstream scientists to think in terms of whole systems, not just isolated variables. Then there are **phenomenology and contemplative studies**: these fields ensure that first-person experience and meaning are not abstracted away when we analyze consciousness. A contemplative scholar might work with a psi researcher to examine, say, the subjective experience of “entanglement” or synchronicity – what does it feel like when a meaningful coincidence occurs, and how might that illuminate the kind of non-local connections MPI formalizes? Likewise, practitioners of meditation or yoga might contribute insights about how mental training seems to increase synchronicities or

intuitive knowing, providing leads for experiments (e.g. testing long-term meditators for entanglement effects versus novices). **No single discipline can crack the mystery of consciousness alone**, especially when it comes to the elusive, shadowy corners where psi resides. By combining rigorous third-person measurements with rich first-person narratives, and by using theoretical frameworks that honor both (like GQT/MPI), we can move toward a more integrative science of consciousness.

One concrete recommendation is to establish joint research programs or think-tanks where parapsychologists, neuroscientists, quantum physicists, and contemplative scholars regularly share data and perspectives. This is already starting in pockets – for example, the **Academy for the Advancement of Postmaterialist Sciences** and various consciousness institutes are bringing meditators and physicists into dialogue. MPI, with its “**no transmission but real correlation**” thesis, could serve as a **common language** in these dialogues. It assures the hard-nosed scientist that we’re not throwing out physics – we’re extending it (via generalized entanglement) – and it assures the experiential researcher that subjective meaning is central, not epiphenomenal. In fact, MPI may help dissolve the outdated **Cartesian cut** between observer and observed, mind and matter, that has hampered both psi acceptance and consciousness studies. If correlations that span mind and matter are empirically verified (even in the subtle ways we’ve discussed), it implies consciousness is **not so inside brains** looking out at a separate world. Rather, **consciousness is something fundamentally interactive** – it *happens between* entities when conditions allow, somewhat like love or communication. This viewpoint encourages researchers to adopt what one might call a “**relational ontology**”: to study consciousness, focus not just on the parts but on the connections, contexts, and wholes.

It’s also worth noting how MPI’s implications foster a kind of **pragmatic humility** among researchers. The lesson that psi cannot be coerced into revealable signals is, metaphorically, a lesson for consciousness science as well: we may not be able to pick down awareness with one explanatory framework or generate it artificially in a silicon chip to prove we understand it. Consciousness, like psi, might withdraw the moment

we try to shine too bright a light on it. This doesn't mean it's fruitless to study – it means we must approach with **reverence and openness to mystery**. As the original article concluded, MPI “re-sacralizes the paranormal” by insisting it unfolds on its own terms. By extension, MPI re-sacralizes consciousness itself. It hints that subjective life, the dance of mind and world, has an irreducible, sacred quality not capturable by reductionist schemas or exploitative agendas. For researchers, the call to **engage with psi and consciousness as participants, not masters**. Instead of saying “prove it to me in my lab,” an MPI-informed scientist might say, “let me enter the scenario where it happens and observe with care.” This aligns with trends in consciousness research that value **neuropsychophenomenology** (the disciplined examination of experience alongside neural data) and ethically-informed experimentation (e.g. studying psychedelics or meditation with respect for the meaningful context of those practices).

In broader culture, embracing MPI's perspective could help heal the rift between scientific and spiritual worldviews. It provides a model wherein **spiritual concepts** **unity, interconnection, and intention** aren't at odds with science, but appear as natural outcomes of systems organizing through shared information gowyrd.org petermerry.org. The idea that “mind and matter are woven into a single tapestry of meaning” ceases to be merely poetic – it becomes a testable (if not directly controllable) hypothesis about correlation. As more evidence accumulates for entanglement in psycho-physical systems, the more credibility will be lent to contemplative insights that have said all along that **consciousness is fundamental & ubiquitous**. We may find common cause between mystics and physicists: both, in their own language, describing a world where the separation between observer and observed is ultimately an illusion petermerry.org.

Finally, the **ethics and purpose** of studying psi and consciousness take on a new light. If we accept that we cannot commodify psi (no psychic communications satellite is coming, no mind-control device will harness entanglement for profit), then the motivation for research shifts from exploitation to understanding. Just as early explorers charted

the stars not to own them but to learn their patterns, today's psi researchers are mapping a facet of reality to enrich human knowledge, not to gain power. This ethic already echoed by leaders in the field: openness, collaboration and **collective benefit over control** are emphasized petermerry.org. For instance, the Global Consciousness Project's evolution (now under the HeartMath Institute) focuses on demonstrating global unity and healing potential, rather than weaponizing mind effects heartmath.org. In academic circles, a similar humility can guide us: rather than asking "*How can we finally prove psi to win over skeptics?*" we might ask "*What do these elusive effects teach us about the nature of consciousness and reality?*". The former mindset seeks a definitive conquest (often leading to fruitless, overhyped "proof" attempts), whereas the latter invites continuous learning and integration in wider scientific understanding.

In summary, MPI's forward-looking message to the science of consciousness is both **challenging and inspiring**. It challenges us to enlarge our framework to include not only local, acausal principles – effectively to naturalize "magic" as just another part of a holistic universe. It inspires us to do so with care and wonder, recognizing that these phenomena are delicate and intertwined with our deepest values and meanings. We are prompted to adopt a kind of **dual attention**: one eye rigorously on data and patterns, one eye reverently on the **depth of significance and subjectivity** that those patterns imply. By engaging psi phenomena *with* the consciousness that participates in them (instead of alienating ourselves as detached manipulators), we may not only advance science, but also enrich our own understanding of what it means to be aware, connected, and alive in an entangled cosmos. The pursuit of psi thus becomes not a quest for a new power, but a **path of co-discovery** – scientists and experiencers together unraveling the subtle threads that link mind to mind, mind to matter, and ultimately, self to universe.

Conclusion

In conclusion, MPI gives us a powerful, if somewhat humbling, lens to view the pantheon of the unexplained. It tells us that behind many hauntings, miracles, and mysteries might lie a single principle: **nonlocal correlations orchestrated by meaning within closed loops of observers and systems**. But it also warns that this principle comes with strict limits – chiefly, the impossibility of harnessing it like a tool or unequivocally proving it in the usual way. Perhaps this is why the **world remains enchanted yet elusive**: those anomalous cracks in the facade of materialism are real but they seal up whenever we shine a spotlight. By appreciating MPI's insights, we learn to study the light and the shadow of psi in tandem – seeking not to trap the firefly in a jar (for its glow would then die), but to understand its dance in the twilight.

Conclusion: The Model of Pragmatic Information offers a robust theoretical scaffold to unify diverse psi phenomena with principles of systems theory and generalized entanglement. It resonates with aspects of quantum consciousness ideas and emergent mind theories, yet stays agnostic about the exact physics, focusing instead on information and meaning. In doing so, MPI validates why psi is so hard to nail down, suggests how we might better approach its study (and why certain grand experiments might falter), and even allows engagement with spiritual concepts of unity and consciousness. It draws a line between what is possible (entanglement correlations yielding genuine anomalies) and what is not (using them for show or profit). In a way, MPI re-sacralizes the paranormal: it must occur *on its own terms*, in its own liminal space, not under klieg lights. For those of us fascinated by the frontier of the mind, MPI is a reminder that the universe may indeed be “woven of connectedness,” but its tapestry is delicate. We can observe and appreciate the patterns – perhaps even generate them – but if we grasp too hard, they vanish, leaving us with just ordinary threads in hand. The true magic, it seems, lies in the interplay of autonomy and connection, of self and other, of knowledge and mystery. MPI invites us to approach psi with both rigor and reverence, keeping one eye on the data and one on the deep significance that might be calling to us through these fleeting windows in the wall of reality.

Sources: The analysis above integrates concepts and findings from Walter von Lucadou's *Model of Pragmatic Information* and related works, Penrose and Hameroff Orch-OR theory, Michael Levin's discussions on emergent intelligence, and Eugene prior deep research articles on psi's elusiveness, the social remote viewing experiment, mainstreaming of esoteric truths, and studies of enlightenment, as well as illustrative examples from parapsychology history. Together, these sources form a mosaic that supports the synthesized perspective presented here.

APPENDIX

RFP: Wyrdoscope Dual-RNG Correlation Experiment

An MPI-Aligned, Multi-Site Open Science Replication Project

Rationale

Even though there have been multiple correlation-style replications (e.g., the Correlation Matrix Method replications at Edinburgh/KPU and a blind-analysis replication by Hartmut Grote at the Max Planck Institute), the evidence is still **not** widely accepted outside parapsychology. A well-run, multi-site, pre-registered Wyrdoscope study—with open data/code and independent replication—**would move the needle** more than “one more” single-lab result. [Edinburgh Research](#)

Here's the landscape in one glance:

- **What exists already:**
 - Von Lucadou's CMM has spawned **replication attempts** (including two replications reported by Edinburgh-affiliated researchers and a doctoral thesis) plus a **blind-analysis** replication by Hartmut Grote (Max Planck), which is visible both in JSE and talks. These show the **pattern is reproducible**, but they live mostly in specialist venues. [Journal of Scientific Exploration](#)
 - Field RNG work (PEAR/GCP) laid groundwork; GCP 2.0 (now at HeartMath) is deploying **dense RNG clusters across ~25 cities/sacred sites**, but its scientific impact is limited.

is ongoing and still needs high-integrity, multi-team confirmatory analyses.

[HeartMath Institute](#)

- **Wyrdoscope**-style tech is now public (IEC 2025 program), but systematic, pre-registered, multi-site publications are still sparse—this is exactly where yo RFP can help. [Integral European Conference](#)

- **Why another study matters:**

Mainstream acceptance hinges less on *one more positive result* and more on **how** obtained: *pre-registration, adversarial collaboration, multi-site replication, and fully open pipelines*. Your ResearchHub RFP can coordinate that format, which existi work has only partially achieved so far. (Think: a “registered report” ethos appl across several independent labs.)

- **Blockchain?**

Useful for notarizing commitments and data manifests, but **not required** to sta The incremental trust gained by hashing prereg plans/data manifests is real, ye the heavy lift comes from clean design and independent replication. (You can a hashes later without changing the core protocol.)

Abstract

This RFP launches a coordinated, multi-site replication using the **Wyrdoscope**, a d quantum-RNG device designed to test **entanglement-like correlations between independent random streams** during meaningful human events (e.g., meditation, group coherence sessions).

Building on the *Model of Pragmatic Information (MPI)*, the study examines whether **acausal correlations** appear in statistically significant form under pre-registered “focus” windows compared to controls—without any attempt to transmit or influen signals.

All sites will follow a shared, open-source protocol, use identical hardware and analysis code, and publicly preregister hypotheses and data pipelines before data collection. Results from all teams will be meta-analyzed and released openly, setting new methodological standard for psi-related mind-matter research.

Impact Statement

While past RNG studies (PEAR, GCP, Correlation Matrix Method) showed promising results, none have yet met contemporary open-science, preregistered, multi-lab standards. This RFP addresses that gap.

By combining **transparent design, independent replication, and adversarial review**, the project aims to convert psi-related findings from fringe curiosity to **testable, reproducible systems science**.

Positive or null, the outcome will advance empirical understanding of **non-local correlations in complex systems** and demonstrate how emerging fields can achieve credibility through rigorous open collaboration.

Summary

This ResearchHub RFP invites labs, physicists, psychologists, data scientists, and open-science practitioners to participate in a **multi-site replication** using the **Wyrdoscope**, a simple device containing two independent quantum random number generators (RNGs).

The goal is to test whether **acausal correlations** between RNGs increase during *meaningful human events* (e.g., meditation, group coherence sessions) compared to matched control periods.

This experiment follows the **Model of Pragmatic Information (MPI)**, which predicts that psi phenomena emerge as **non-causal correlations** within closed, meaning-rich systems—not as directed signals. It directly tests the core MPI prediction while meeting the highest methodological and skeptical standards.

Why This Matters

- **Replicability gap:** Existing studies (von Lucadou's Correlation Matrix Method, PEAR FieldREG, GCP) show consistent but under-replicated results. A rigorous pre-registered, adversarial, multi-site effort can *transform credibility*.

- **Skeptic-proof design:** The study is observational, statistical, and cannot be used to “send signals.” All data and code will be public, and analyses pre-committed.
- **Low-cost and scalable:** Each Wyrdoscope node costs <\$1.2k and can be run in lab or field events.
- **Public transparency:** All sites follow the same preregistered plan, use identical hardware/software, and contribute data for pooled meta-analysis.

Experimental Design (Core Protocol)

Hardware (per site)

- Wyrdoscope device (dual independent quantum RNGs)
- Raspberry Pi or NUC logger (1 Hz binning)
- GPS/NTP time-sync module
- Simple UI for logging event start/stop

Procedure

1. Record both RNGs continuously.
2. Mark *focus windows* (group meditation, ceremony, or collective quiet).
3. Record *control windows* at same time of day, different days.
4. Compute **Pearson correlation and mutual information** between RNG A and B across all windows.
5. Compare focus vs. control distributions with permutation tests.
6. Aggregate results across sites (meta-analytic Fisher z).

Primary Endpoint

Mean zero-lag correlation (1 s binned data) between RNG A & B is greater during pre-registered focus windows than matched control windows (two-tailed $\alpha = 0.05$)

Secondary Endpoints

Short-lag cross-correlation (± 5 s), mutual information, entropy/variance changes.

Power Target

$\geq 20\,000$ seconds of focus data per site (≈ 6 hours) $\rightarrow$ detect $r \approx 0.02$ with $> 80\%$ power

Adversarial Collaboration and Best Practices

- **Open preregistration:** Each site posts its analysis plan, code hash, window schedule, and exclusion rules on **OSF** or **ResearchHub** before data collection.
- **Adversarial review:** At least one external methodologist/skeptic will review and sign off on the preregistration.
- **Common analysis container:** Docker/Colab pipeline (Python/R) shared in advance to ensure identical analyses.
- **No real-time dashboards:** To preserve MPI “organizational closure” and prevent signal-intent collapse.
- **Mandatory data release:** Raw RNG files, metadata, and code uploaded to OSF or Zenodo within 2 weeks post-session.

NT-Axiom Compliance

This study does **not** instruct participants to generate any specific outcome.

Correlations emerge—if they do—spontaneously and cannot carry information or be predicted in advance. Thus, no violation of physical causality or MPI’s Non-Transmission axiom occurs; we only detect **acausal statistical structure** after the fact.

Deliverables

Each participating team must submit:

1. Raw RNG logs + metadata
2. Confirmed hardware independence tests (RNG A vs B autocorrelation < 0.001)

3. Pre-registered analysis notebook and output report (effect size, p-values, confidence intervals)
4. Independent verification run using the shared analysis container
5. Final summary posted on ResearchHub for pooled meta-analysis

Funding & Timeline

Phase	Deliverable	Est. Duration
1	Protocol finalization, preregistration templates	4 weeks
2	Kit distribution + local calibration	4 weeks
3	First data collection & upload	8 weeks
4	Meta-analysis & publication	12–16 weeks

Estimated cost per site: \$800–\$1,200 hardware, \$500–\$1,000 local stipend.

Core coordination budget: \$15 k (software + data hub + meta-analysis).

Success Criteria

- ≥ 3 independent teams complete preregistered runs.
- Pooled meta-analytic result $p < 0.05$ (two-tailed).
- All raw data and code publicly verifiable.
- Endorsements or re-analyses by independent skeptics/statisticians.

How to Participate

1. Comment or apply on this RFP page with your institution, lab capabilities, and preferred site context (lab, meditation group, event).
2. You'll receive the Wyrdoscope hardware design and software container.
3. Confirm preregistration before your first run.
4. Upload raw data and reports according to the shared protocol.

The Psychokinetic TalksThe Psychokinetic TalksNov 19, 2025

Psychokinesis is simply active inference by the universe to reduce the free energy that would produced according to the Free Energy Principle of cognition and the mind if a high certainty, precision prediction made by a sentient being about an applied intention (healing a wound, moving an object, bending a spoon) was not manifested. I write about all of this on my substack. I'm convinced this is the best model we have at the moment. What's so neat about it is that it gives direct paths forward to enhance our ability to generate high precision, high certainty predictions about the outcome of our applied intentions. Primarily, meditation. If anyone is interested in discussing these concepts, please contact me here on substack.
